Package 'BiodiversityR'

April 16, 2015

Type Package

Title Package for Community Ecology and Suitability Analysis
Version 2.5-2
Date 2015-04-09
Author Roeland Kindt
Maintainer Roeland Kindt < R.KINDT@CGIAR.ORG>
Description Graphical User Interface (via the R-Commander) and utility functions (often based on the vegan package) for statistical analysis of biodiversity and ecological communities, including species accumulation curves, diversity indices, Renyi profiles, GLMs for analysis of species abundance and presence-absence, distance matrices, Mantel tests, and cluster, constrained and unconstrained ordination analysis. A book on biodiversity and community ecology analysis is available for free download from the website. In 2012, methods for (ensemble) suitability modelling and mapping were expanded in the package.
License GPL-2

BiodiversityR-package GUI for biodiversity, suitability and community ecology analysis

Description

This package provides a GUI (Graphical User Interface, via the R-Commander; BiodiversityRGUI) and some utility functions (often based on the vegan package) for statistical analysis of biodiversity and ecological communities, including species accumulation curves, diversity indices, Renyi profiles, GLMs for analysis of species abundance and presence-absence, distance matrices, Mantel tests, and cluster, constrained and unconstrained ordination analysis. A book on biodiversity and community ecology analysis is available for free download from the website.

Details

We warmly thank all that provided inputs that lead to improvement of the Tree Diversity Analysis manual that describes common methods for biodiversity and community ecology analysis and its accompanying software. We especially appreciate the comments received during training sessions with draft versions of this manual and the accompanying software in Kenya, Uganda and Mali. We are equally grateful to the thoughtful reviews by Dr Simoneta Negrete-Yankelevich (Instituto de Ecologia, Mexico) and Dr Robert Burn (Reading University, UK) of the draft version of this manual, and to Hillary Kipruto for help in editing of this manual. We also want to specifically thank Mikkel Grum, Jane Poole and Paulo van Breugel for helping in testing the packaged version of the software. We also want to give special thanks for all the support that was given by Jan Beniest, Tony Simons and Kris Vanhoutte in realizing the book and software.

We highly appreciate the support of the Programme for Cooperation with International Institutes (SII), Education and Development Division of the Netherlands Ministry of Foreign Affairs, and VVOB (The Flemish Association for Development Cooperation and Technical Assistance, Flanders, Belgium) for funding the development for this manual. We also thank VVOB for seconding Roeland Kindt to the World Agroforestry Centre (ICRAF). The tree diversity analysis manual was inspired by research, development and extension activities that were initiated by ICRAF on tree and landscape diversification. We want to acknowledge the various donor agencies that have funded these activities, especially VVOB, DFID, USAID and EU.

We are grateful for the developers of the R Software for providing a free and powerful statistical package that allowed development of BiodiversityR. We also want to give special thanks to Jari Oksanen for developing the vegan package and John Fox for developing the Rcmdr package, which are key packages that are used by BiodiversityR.

We suggest to use this citation for this software as well (together with citations of all other packages that were used)

accumresult

Alternative Species Accumulation Curve Results

Description

Provides alternative methods of obtaining species accumulation results than provided by functions specaccum and plot.specaccum (vegan).

Usage

Arguments

x	Community data frame with sites as rows, species as columns and species abundance as cell values.
у	Environmental data frame.
factor	Variable of the environmental data frame that defines subsets to calculate species accumulation curves for.
level	Level of the variable to create the subset to calculate species accumulation curves.
scale	Continuous variable of the environmental data frame that defines the variable that scales the horizontal axis of the species accumulation curves.
method	Method of calculating the species accumulation curve (as in function specaccum). Method "collector" adds sites in the order they happen to be in the data, "random" adds sites in random order, "exact" finds the expected (mean) species richness, "coleman" finds the expected richness following Coleman et al. 1982, and "rarefaction" finds the mean when accumulating individuals instead of sites.
permutations	Number of permutations to calculate the species accumulation curve (as in function specaccum).
conditioned	Estimation of standard deviation is conditional on the empirical dataset for the exact SAC (as in function specaccum).
gamma	Method for estimating the total extrapolated number of species in the survey area (as in specaccum).

accumresult 5

addit	Add species accumulation curve to an existing graph.
xr	Result from specaccum or accumresult.
col	Colour for drawing lines of the species accumulation curve (as in function plot.specaccum).
labels	Labels to plot at left and right of the species accumulation curves.
ci	Multiplier used to get confidence intervals from standard deviatione (as in function plot.specaccum).
pch	Symbol used for drawing the species accumulation curve (as in function points).
type	Type of plot (as in function plot).
cex	Character expansion factor (as in function plot).
xlim	Limits for the horizontal axis.
ylim	Limits for the vertical axis.
xlab	Label for the horizontal axis.
ylab	Label for the vertical axis.
plotit	Plot the results.
labelit	Label the species accumulation curves with the levels of the categorical variable.
legend	Add the legend (you need to click in the graph where the legend needs to be plotted).
rainbow	Use rainbow colouring for the different curves.
	Other items passed to function specaccum or plot.specaccum.

Details

These functions provide some alternative methods of obtaining species accumulation results, although function specaccum is called by these functions to calculate the actual species accumulation curve.

Functions accumresult and accumcomp allow to calculate species accumulation curves for subsets of the community and environmental data sets. Function accumresult calculates the species accumulation curve for the specified level of a selected environmental variable. Method accumcomp calculates the species accumulation curve for all levels of a selected environmental variable separatedly. Both methods allow to scale the horizontal axis by multiples of the average of a selected continuous variable from the environmental dataset (hint: add the abundance of each site to the environmental data frame to scale accumulation results by mean abundance).

Functions accumcomp and accumplot provide alternative methods of plotting species accumulation curve results, although function plot. specaccum is called by these functions. When you choose to add a legend, make sure that you click in the graph on the spot where you want to put the legend.

Value

The functions provide alternative methods of obtaining species accumulation curve results, although results are similar as obtained by functions specaccum and plot.specaccum.

http://www.worldagroforestry.org/resources/databases/tree-diversity-analysis

Examples

```
library(vegan)
data(dune.env)
data(dune)
dune.env$site.totals <- apply(dune,1,sum)
Accum.1 <- accumresult(dune, y=dune.env, scale='site.totals', method='exact', conditioned=TRUE)
Accum.1
accumplot(Accum.1)
accumcomp(dune, y=dune.env, factor='Management', method='exact', legend=FALSE, conditioned=TRUE)
## CLICK IN THE GRAPH TO INDICATE WHERE THE LEGEND NEEDS TO BE PLACED FOR
## OPTION WHERE LEGEND=TRUE (DEFAULT).</pre>
```

add.spec.scores

Add Species Scores to Unconstrained Ordination Results

Description

Calculates scores (coordinates) to plot species for PCoA or NMS results that do not naturally provide species scores. The function can also rescale PCA results to use the choice of rescaling used in **vegan** for the rda function (after calculating PCA results via PCoA with the euclidean distance first).

Usage

```
add.spec.scores(ordi,comm,method="cor.scores",multi=1,Rscale=F,scaling="1")
```

Arguments

comm

ordi	Ordination result as calculated by cmdscale, isoMDS, sammon, postMDS, metaMDS
	or NMS random

Community data frame with sites as rows, species as columns and species abun-

dance as cell values.

method Method for calculating species scores. Method "cor.scores" calculates the scores

by the correlation between site scores and species vectors (via function cor), method "wa.scores" calculates the weighted average scores (via function wascores) and method "pcoa.scores" calculates the scores by weighing the correlation between site scores and species vectors by variance explained by the ordination

axes.

multi Multiplier for the species scores.

Rscale Use the same scaling method used by **vegan** for rda.

scaling Scaling method as used by rda.

balanced.specaccum 7

Value

The function returns a new ordination result with new information on species scores. For PCoA results, the function calculates eigenvalues (not sums-of-squares as provided in results from function cmdscale), the percentage of explained variance per axis and the sum of all eigenvalues. PCA results (obtained by PCoA obtained by function cmdscale with the Euclidean distance) can be scaled as in function rda, or be left at the original scale.

Examples

balanced.specaccum

Balanced Species Accumulation Curves

Description

Provides species accumulation results calculated from balanced (equal subsample sizes) subsampling from each stratum. Sites can be accumulated in a randomized way, or alternatively sites belonging to the same stratum can be kept together Results are in the same format as specaccum and can be plotted with plot.specaccum (vegan).

Usage

```
balanced.specaccum(comm, permutations=100, strata=strata, grouped=TRUE,
    reps=0, scale=NULL)
```

8 balanced.specaccum

Arguments

comm Community data frame with sites as rows, species as columns and species abun-

dance as cell values.

permutations Number of permutations to calculate the species accumulation curve.

strata Categorical variable used to specify strata.

reps Should sites from the same stratum be kept together (TRUE) or not.

Number of subsamples to be taken from each stratum (see details).

Scale Quantitative variable used to scale the sampling effort (see details).

Details

This function provides an alternative method of obtaining species accumulation results as provided by specaccum and accumresult.

Balanced sampling is achieved by randomly selecting the same number of sites from each stratum. The number of sites selected from each stratum is determined by reps. Sites are selected from strata with sample sizes larger or equal than reps. In case that reps is smaller than 1 (default: 0), then the number of sites selected from each stratum is equal to the smallest sample size of all strata. Sites from the same stratum can be kept together (grouped=TRUE) or the order of sites can be randomized (grouped=FALSE).

The results can be scaled by the average accumulation of a quantitative variable (default is number of sites), as in accumresult (hint: add the abundance of each site to the environmental data frame to scale accumulation results by mean abundance). When sites are not selected from all strata, then the average is calculated only for the strata that provided sites.

Value

The functions provide alternative methods of obtaining species accumulation curve results, although results are similar as obtained by functions specaccum and accumresult.

BCI.env 9

Examples

```
library(vegan)
data(dune.env)
data(dune)
# randomly sample 3 quadrats from each stratum of Management
Accum.1 <- balanced.specaccum(dune, strata=dune.env$Management, reps=3)
Accum.1
dune.env$site.totals <- apply(dune,1,sum)
# scale results by number of trees per quadrat
Accum.2 <- balanced.specaccum(dune, strata=dune.env$Management, reps=3, scale=dune.env$site.totals)
Accum.2</pre>
```

BCI.env

Barro Colorado Island Quadrat Descriptions

Description

Topography-derived variables and UTM coordinates and UTM coordinates of a 50 ha sample plot (consisting of 50 1-ha quadrats) from Barro Colorado Island of Panama. Dataset BCI provides the tree species composition (trees with diameter at breast height equal or larger than 10 cm) of the same plots.

Usage

```
data(BCI.env)
```

Format

A data frame with 50 observations on the following 6 variables.

UTM.EW UTM easting

UTM.NS UTM northing

elevation mean of the elevation values of the four cell corners

convex mean elevation of the target cell minus the mean elevation of the eight surrounding cells

slope mean angular deviation from horizontal of each of the four triangular planes formed by connecting three of its corners

aspectEW the sine of aspect

aspectNS the cosine of aspect

BiodiversityRGUI

GUI for Biodiversity Analysis and Ordination

Description

This function provides a GUI (Graphical User Interface) for some of the functions of **vegan**, some other packages and some new functions to run biodiversity analysis, including species accumulation curves, diversity indices, Renyi profiles, rank-abundance curves, GLMs for analysis of species abundance and presence-absence, distance matrices, Mantel tests, cluster and ordination analysis (including constrained ordination methods such as RDA, CCA, db-RDA and CAP). The function depends and builds on **Rcmdr**, performing all analyses on the community and environmental datasets that the user selects. A thorough description of the package and the biodiversity and ecological methods that it accomodates (including examples) is provided in the freely available Tree Diversity Analysis manual (Kindt and Coe, 2005).

Usage

BiodiversityRGUI()

Details

The function launches the R-Commander GUI with an extra menu list for common statistical methods for biodiversity and community ecology analysis.

The R-Commander is launched by changing the location of the Rcmdr "etc" folder to the "etc" folder of BiodiversityR. As the files of the "etc" folder of BiodiversityR are copied from Rcmdr 1.3-14, it is possible that newer versions of the R-Commander will not be launched properly. In such situations, it is possible that copying all files from the Rcmdr "etc" folder again and adding the BiodiversityR menu options to the Rcmdr-menus.txt is all that is needed to launch the R-Commander again.

BiodiversityR uses two data sets for analysis: the community dataset (or community matrix or species matrix) and the environmental dataset (or environmental matrix). The environmental dataset is the same dataset that is used as the "active dataset" of The R-Commander. (Note that you could sometimes use the same dataset as both the community and environmental dataset. For example, you could use the community dataset as environmental dataset as well to add information about specific species to ordination diagrams. As another example, you could use the environmental dataset as community dataset if you first calculated species richness of each site, saved this information in the environmental dataset, and then use species richness as response variable in a regression analysis.) Some options of analysis of ecological distance allow the community matrix to be a distance

matrix (the community data set will be interpreted as distance matrix via as.dist prior to further analysis).

BiodiversityR provides the following menu options (each described below in greater detail):

- Select community dataset (Community matrix menu) Selects a dataset to be the community dataset.
- Import datasets from Excel (Community matrix menu) Imports a community and environmental dataset from an Excel workbook (only applies to a Windows OS).
- Import datasets from Access (Community matrix menu) Imports a community and environmental dataset from an Access database (only applies to a Windows OS).
- View community data set (Community matrix menu) Invoke the R text editor to view the data of the community data set.
- Edit community data set (Community matrix menu) Invoke the R text editor to edit the data of the community data set.
- Check data sets (Community matrix menu) Check whether the community and environmental data sets have compatible dimensions.
- Same sites for community and environmental (Community matrix menu) Creates a new community dataset with the same sites sequence as the environmental matrix.
- Make community dataset (Community matrix menu) Creates a community dataset from the environmental dataset.
- **Remove NA** (Community matrix menu) Removes the same sites with NA from the environmental and community datasets.
- Transform community matrix (Community matrix menu) Transforms the community matrix.
- Select environmental data set (Environmental matrix menu) Selects a dataset to be the environmental dataset.
- View environmental data set (Environmental matrix menu) Invoke the R text editor to view the data of the environmental dataset.
- Edit environmental data set (Environmental matrix menu) Invoke the R text editor to edit the data of the environmental dataset.
- Summary (Environmental matrix menu) Explores variables of the environmental dataset.
- **Box Cox transformation** (Environmental matrix menu) Creates a transformed variable from one of the variables of the environmental dataset.
- Species accumulation curves (Analysis of diversity menu) Estimates and plots species accumulation curves.
- Diversity indices (Analysis of diversity menu) Calculates and plots diversity indices.
- Rank abundance (Analysis of diversity menu) Calculates and plots rank-abundance curves.
- Renyi profile (Analysis of diversity menu) Calculates and plots Renyi diversity profiles.
- Species abundance as response (Analysis of species as response menu) Fits and plots regression models assuming that the response variable is count data.
- Species presence-absence as response (Analysis of species as response menu) Fits and plots regression models transforming and analysing the response variable as presence-absence.

• Calculate distance matrix (Analysis of ecological distance menu) Calculates a distance matrix.

- Unconstrained ordination (Analysis of ecological distance menu) Fits and plots unconstrained ordination models.
- Constrained ordination (Analysis of ecological distance menu) Fits and plots constrained ordination models.
- Clustering (Analysis of ecological distance menu) Calculates and plots results from clustering algorithms.
- Compare distance matrices (Analysis of ecological distance menu) Conducts some analysis such as Mantel, MRPP and ANOSIM tests on distance matrices.
- **Help about BiodiversityR** (Help menu) Opens the help file available for the BiodiversityR package (including this html file).
- **Citations for loaded packages** (Help menu) Provides a list of all the loaded packages and gives citation information.
- Go to website for BiodiversityR (Help menu) Links to the website for the BiodiversityR package and Tree Diversity Analysis manual.
- Tree diversity analysis manual (Help menu) Links to the PDF version of the Tree Diversity Analysis manual. Separate chapters can be downloaded from the website of BiodiversityR (see directly above).

Value

None

Select Community Dataset

This window selects the community dataset to be used in the biodiversity analyses and provides the following options:

- Data Sets (pick one) A drop-down list is provided with all the datasets that are available. The current community data set is indicated, or the first data set of the list is shown. New datasets can be loaded through the Data menu of the Rcmdr or through the "import from Excel" option of BiodiversityR (only Windows OS).
- **OK** Make the selected data set the community data set.
- Cancel Close the window and do not select a new data set.

Same sites for community and environmental datasets

This window maps the community dataset onto the rownames of the environmental dataset by function same.sites. Having the same sequence of sites is an assumption for analysis with BiodiversityR. It may be useful to use this function after making a community dataset from a stacked environmental dataset (especially as sites are ordered in an alphabetic way from the stacked dataset, which may create problems with X1, X10, X100 site names versus the X001, X010 and X100 formats; the function is also useful where some sites do not contain any species). The menu provides the following options:

• save original community matrix If this option is selected, the original data set is saved under the name of the community dataset followed by ".orig".

- **OK** Order the sites of the community dataset in exactly the same way as the sites of the environmental data set, leaving out sites that do not have matching names in the environmental data set.
- Cancel Close the window and do not re-order and select the sites.

Make Community Dataset

This window selects the variables that indicates sites, species and abundance to create a new community dataset. This dataset becomes the active community dataset. The menu provides the following options:

- Save result as The name for the new community dataset.
- **Site variable (rows)** The list shows the variables that can be used for the names of sites (shown as names for the rows). Passed as argument for "row" of function makecommunitydataset.
- Species variable (columns) The list shows the variables that can be used for the names of species (shown as names for the columns). Passed as argument for "column" of function makecommunitydataset.
- Abundance variable The list shows the variables that can be used for the abundance values (shown as totals for cells). Passed as argument for "value" of function makecommunitydataset.
- **Subset options** The list shows the variables that can be used for the abundance values (shown as totals for cells). Passed as argument for "factor" of function makecommunitydataset.
- **Subset** Chooses the value for the subset variable to create the subset. Passed as argument for "level" of function makecommunitydataset.
- **OK** Create the community data set and make it the active community dataset.
- Cancel Close the window and do not create a new community dataset.

Remove NA

This window removes the sites that have NA (missing values) for a selected variable of the environmental dataset. When environmental variables have missing values, this often creates problems with biodiversity analysis. The menu provides the following options:

- **Select variable** The list shows the variables that can be used to remove sites with NA. Passed as argument for var for functions removeNAcomm and removeNAenv.
- **OK** Remove the sites with NA.
- Cancel Close the window and do not remove the sites with NA.

Transform community matrix

This window transforms the community matrix. The menu provides the following options:

• Method Method of transforming the community dataset. Passed as argument for "method" for function distransform. The transformed community matrix is saved under the same name of the original dataset, and the current community dataset therefore becomes the transformed community dataset.

• Save original community matrix This option saves the untransformed community dataset by adding .orig to the name of the community dataset, as the function replaces the original dataset with the transformed community dataset.

- **OK** Calculate the new community matrix.
- Cancel Close the window and do not calculate a new community matrix.

Select Environmental Dataset

This window selects the environmental dataset to be used in the biodiversity analyses. The environmental dataset is always the active dataset for non-Biodiversity Rcmdr options. By selecting the community dataset as the environmental dataset as well, you can also manipulate the community dataset with the other Rcmdr options. The menu provides the following options:

- Data Sets (pick one) A drop-down list is provided with all the datasets that are available. The current community data set is indicated, or the first data set of the list is shown. New datasets can be loaded through the Data menu of the Rcmdr or through the "import from Excel" option of BiodiversityR (only in Windows OS).
- OK Make the selected data set the environmental data set.
- Cancel Close the window and do not select a new data set.

Summary

This window makes a summary of all or a selection of the variables of the environmental dataset, or plots the variables. In case that you want to make a summary of the community dataset, then you need to make the community dataset the environmental dataset at the same time. The menu provides the following options:

- **Select variable** A drop-down list is provided with all the variables of the environmental dataset. The first item of the list (all) is reserved to make a summary of all variables, datasets that are available.
- **OK** Make a summary of all variables or the selected variable by function summary.
- **Plot** Plots all variables against each other with function pairs, plots a selected continuous variable with function plot or plots a categorical with function boxplot.
- Cancel Close the window and do provide any summary or plot.

Box Cox transformation

This window makes a Box-Cox transformation of a selected variable from the environmental dataset. The menu provides the following options:

- **Select variable** A drop-down list is provided with all the variables of the environmental dataset. Click on the variable to transform.
- **OK** Calculates a Box-Cox transformation of the selected variable with function box.cox.powers. Makes a QQ-plot (function qq.plot), and performs a Shapiro test (function shapiro.test) and Kolmogorov-Smirnov test (function ks.test) of the original and transformed variable.
- Cancel Close the window.

Species accumulation curves

This window fits and plots species accumulation curves. The menu provides the following options:

- Save result as The name for the new object that will save the results from the estimated species accumulation curve after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you plot the result by typing in the name of previous result first in this box.
- Accumulation method Select the method of species accumulation. Passed as argument for "method" of functions accumresult or accumcomp.
- **permutations** Number of permutations for random species accumulation. Passed as argument for "permutation" of functions accumresult or accumcomp.
- scale of x axis Method of scaling the horizontal axis. Passed as argument for "scale" of functions accumresult or accumcomp.
- **subset options** The list shows the variables that can be used for selecting subsets. Option "all" indicates that no subset will be calculated. In case a variable is selected, it will be passed as argument for "factor" of functions accumresult or accumcomp.
- Subset Subset chooses which subsets are calculated. In case that the value of "." (a period) is selected then function accumcomp will used to calculate the species accumulation curve and to plot the curve (you may need to click in the graph to show where the legend needs to be placed). In case another value is chosen, then this will be the argument for "level" of function accumresult.
- **Plot options** Options for plotting passed to function accumplot.

Option "addplot" sets "addit=T" meaning that the species accumulation curve will be added to an existing graph.

Option "x limits"sets "xlim". Providing "1,10" will plot between 1 and 10.

Option "y limits" sets "ylim". Providing "2,20" will plot between 2 and 20.

Option "ci"sets "ci".

Option "symbol" sets "pch".

Option "cex"sets "cex".

Option "colour" sets "col".

- **OK** Calculate the species accumulation curve with functions functions accumresult or accumcomp.
- **Plot** Plot the species accumulation curve with the name listed on top with function accumplot. You may need to click in the graph to indicate where the legend needs to be placed.
- Cancel Close the window and do not calculate a new species accumulation curve.

Diversity indices

The window calculates and fits diversity indices from the community dataset. The menu provides the following options:

• Save result as The name for the new object that will save the results from the estimated diversity indices after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you plot the result by typing in the name of previous result first in this box. To obtain a meaningful graph, you need to provide similar selections as for the original result (and it may thus be easier to recalculate first and then plot immediately).

• **Diversity index** Select the diversity index. Passed as argument for "index" of functions diversityresult or diversitycomp.

- **Calculation method** Select the method of calculation. Passed as argument for "method" of functions diversityresult or diversitycomp.
- **subset options** The list shows the variables that can be used for selecting subsets. Option "all" indicates that no subset will be calculated. In case a variable is selected, it will be passed as argument for "factor" of functions diversityresult or diversitycomp.
- **Subset** Subset chooses which subsets are calculated. In case that the value of "." (a period) is selected then function diversitycomp will used to calculate the species accumulation curve and to plot the curve (you may need to click in the graph to show where the legend needs to be placed). In case another value is chosen, then this will be the argument for "level" of function diversityresult.
- **Output options** Options for obtaining results with functions diversityresult, diversitycomp or for plotting results.

Option "save results" results in adding a new variable with the diversity indices to the environmental dataset. This method only works for calculation method "separate per site" and function diversityresult.

Option "sort results" results in setting option "sortit=T" for functions diversityresult or diversitycomp.

Option "label results" results in labeling points in the resulting graph.

Option "add plot" results in adding points to an existing graph.

Option "y limits" results in setting limits for the y axis. Providing "0,10" results in limits of 0 and 10 for the vertical axis.

Option "symbol" sets "pch" to choose symbols as in function points.

- **OK** Calculate the diversity indices with diversityresult or diversitycomp.
- **Plot** Plot the diversity results with the name listed on top (should have been calculated first). This will only provide meaningful results if similar options are provided as when calculating the results.
- Cancel Close the window and do not calculate new diversity indices.

Rank Abundance

The window fits and plots rank abundance curves for the community dataset. The menu provides the following options:

- Save result as The name for the new object that will save the results from the estimated rank abundance curve after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you plot the result by typing in the name of previous result first in this box.
- **subset options** The list shows the variables that can be used for selecting subsets. Option "all" indicates that no subset will be calculated. In case a variable is selected, it will be passed as argument for "factor" of functions rankabundance or rankabuncomp.
- Subset Subset chooses which subsets are calculated. In case that the value of "." (a period) is selected then function rankabuncomp will used to calculate and plot the rank abundance curves (you may need to click in the graph to show where the legend needs to be placed). In case another value is chosen, then this will be the argument for "level" of function rankabundance.

• **Plot options** The list provides options for scaling the vertical axis. The selection is passed as argument for "scale" of function rankabunplot.

Option "fit RAD" fits distribution models to the observed rank-abundance distribution with function radfitresult and plots the results.

Option "add plot" sets addit=T for function rankabunplot meaning that the rank abundance curve will be added to an existing graph.

Option "x limits" sets xlim for function rankabunplot. Providing "1,10" will plot between 1 and 10.

Option "y limits" sets ylim for function rankabunplot. Providing "2,20" will plot between 2 and 20.

- **OK** Calculate the rank abundance curve with functions rankabundance or rankabuncomp.
- **Plot** Plot the rank abundance curve with the name listed on top (should have been calculated first) with function rankabunplot, or fit models to rank abundance distribution.
- Cancel Close the window and do not calculate a new rank abundance curve.

Renyi diversity profiles

The window fits and plots Renyi diversity profiles from the community dataset. The menu provides the following options:

- Save result as The name for the new object that will save the results from the diversity profiles after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you plot the result by typing in the name of previous result first in this box.
- Calculation method The list allows to select the method of calculating the diversity profile.

 Options "all" and "separate per site" are passed as argument for "method" of function renyiresult.

 Option "accumulation" results in using function renyiaccumresult.

 These options are not valid when renyicomp is invoked (see Subset options).
- Scale parameters The "scale parameters" are passed as argument for "scale" for functions renyiresult, renyiaccumresult or renyicomp.
- **Permutations** The "permutations" are passed as argument for "permutations" for functions renyiaccumresult or renyicomp.
- **subset options** The list shows the variables that can be used for selecting subsets. Option "all" indicates that no subset will be calculated.
 - In case a variable is selected, it will be passed as argument for "factor" of functions renyiresult or renyicomp.
- Subset Subset chooses which subsets are calculated. In case that the value of "." (a period) is selected then function renyicomp will used to calculate the diversity profile and to plot the curve (you may need to click in the graph to show where the legend needs to be placed). In case another value is chosen, then this will be the argument for "level" of function renyiresult.
- Plot options Options for plotting passed to function renyiplot.
 Option "evenness profile" sets "evenness=T".
 Option "evenness profile" sets addit=T meaning that the diversity profiles will be added to an existing graph.

Option "y limits" sets ylim. Providing "2,20" will plot between 2 and 20.

Option "symbol" sets pch.

Option "cex"sets cex.

Option "colour" sets col.

- **OK** Calculate the diversity profile with functions renyiresult, renyiaccumresult or renyicomp.
- **Plot** Plot the species accumulation curve with the name listed on top with functions renyiplot or persp.renyiaccum. The calculation method will determine which plot function is used.
- Cancel Close the window and do not calculate a new diversity profile.

Species abundance as response

The window fits and plots regression models for abundance data with a response variable selected from the community dataset and explanatory variables selected from the environmental dataset. (Hint: to analysis species richness patterns, save site-specific species richness (from diversity indices menu) into the environmental data set, and then make the environmental data set to be the community dataset as well). The menu provides the following options:

- Save result as The name for the new object that will save the results from the fitted regression model after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you can plot the result by typing in the name of previous result first in this box.
- Model options Select the method of regression analysis.

Option "linear model" fits a simple linear regression model with function 1m.

Option "Poisson model" fits GLMs with Poisson variance functions and log link functions through function glm.

Option "quasi-Poisson model" fits GLMs with quasi-Poisson variance functions and log link functions through function glm.

Option "negative binomial model" fits GLMs with negative binomial variance functions and log link functions through function glm.nb.

Option "gam model" fits GAMs with Poisson variance functions and log link functions through function gam..

Option "gam negbinom model" fits GAMs with negative binomial variance functions and log link functions through function gam.

Option "glmmPQL" fits GLMMs with negative binomial variance functions and log link functions through function glmmPQL.

Option "rpart" fits a regression tree through function rpart.

- **Standardize** Fit the regression to a standardised dataset with function scale (only continuous variables are standardised, not categorical variables).
- **Print summary** Provide a summary of the regression with functions summary.lm, summary.glm or summary.gam.
- **Print anova** Provide a summary of the regression with functions anova.lm, anova.glm, anova.gam, drop1 or Anova (latter two type-II ANOVAs only invoced for multiple regression).
- add predictions to data frame Adds the predicted values to the environmental dataset using the model name combined with ".fit" (using the appropriate predict function).

• **Response variable** Type the name of the response variable, or select and double-click from the list that is provided. This variable will be displayed on the left-hand side of the formula (variable ~) and is also the response variable that is plotted in the various result plots. The variable is selected as one of the variables (species) of the community dataset, and is first added to the environmental dataset. When you select the environmental dataset to be the community dataset as well, then you can select variables of the environmental dataset as response variable.

- Explanatory Type the right-hand side of the model formula (~ explanatory), or select and double-click for variables and select and click for operators to construct the right-hand side of the model formula.
- Remove site with name The name of the site to be removed from the environmental dataset.
- **Plot options** The options provide various functions that can be used to plot regression results of the current model (shown on top of the window; should have been estimated first).

Option "diagnostic plots" chooses functions plot.lm or gam.check to plot diagnostic plots. For regression trees, the residuals are plotted against the residuals via predict.rpart and residuals.rpart.

Option "levene test" chooses function levene. test and plots residuals of the selected categorical variable (shown on the right).

Option "term plot" chooses functions termplot or plot. gam to plot a termplot of the selected categorical variable (shown on the right).

Option "effect plot" chooses function effect to plot an effect plot of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables).

Option "qq plot" chooses function qq.plot to plot the residuals from the model.

Option "result plot (new)" chooses an appropriate predict function to plot a new plot of the model predictions for the selected variable (shown on the right).

Option "result plot (add)" chooses an appropriate predict function to add a new plot of the model predictions for the selected variable (shown on the right)

Option "result plot (interpolate)" chooses an appropriate predict function to add a new plot of the model predictions for the selected variable (shown on the right). This model is predicted from a new dataset that only contains 1000 interpolated values for the selected explanatory variable.

Option "cr plot" chooses function cr.plots to plot a component + residual plots of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables).

Option "av plot" chooses function av.plots to plot added variable plots of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables and has an option of identifying sites with the mouse.)

Option "influence plot" chooses function influence.plot to plot influence plots. (The menu option of the R-Commander of models > Graphs includes the option of identifying sites with the mouse.)

Option "multcomp" chooses function glht to plot simultaneous confidence intervals of the selected categorical variable (shown on the right).

Option "rpart" chooses functions plot.rpart and text.rpart to plot a dendrogram for the regression tree result.

• Plot variable Variable of the environmental dataset that is used for some plotting functions.

- **OK** Fit the selected models.
- **Plot** Plot results for the model with name that appears on top. The model options need to apply to the model (e.g. if a GLM method was used to fit the model, this option should also be selected when plotting the results).

• Cancel Close the window and do not estimate new regression models.

Species presence-absence as response

The window fits and plots regression models for presence-absence data with a response variable selected from the community dataset and explanatory variables selected from the environmental dataset. The menu provides the following options:

- Save result as The name for the new object that will save the results from the fitted regression model after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you can plot the result by typing in the name of previous result first in this box.
- **Model options** Select the method of regression analysis.

Option "crosstab" calculates a cross-tabulation of the selected response (rescaled as presenceabsence) and one selected environmental variable, and estimates a Chi-square test of the contingency table with function chisq.test.

Option "binomial model" fits GLMs with binomial variance functions and logit link functions through function glm.

Option "quasi-binomial model" fits GLMs with quasi-binomial variance functions and log link functions through function glm.

Option "gam model" fits GAMs with binomial variance functions and logit link functions through function gam.

Option "gam quasi-binomial model" fits GAMs with quasi-binomial variance functions and logit link functions through function gam.

Option "rpart" fits a regression tree through function rpart.

Option "nnet" fits a forward-feeding artificial neural network through function nnetrandom.

- **Standardize** Fit the regression to a standardised dataset with function scale (only continuous variables are standardised, not categorical variables).
- **Print summary** Provide a summary of the regression with functions summary.glm or summary.gam, or use summary.rpart or summary.nnet
- **Print anova** Provide a summary of the regression with functions anova.glm, anova.gam, drop1 or Anova (latter two type-II ANOVAs only invoced for multiple regression).
- add predictions to data frame Adds the predicted values to the environmental dataset using the model name combined with ".fit" (using the appropriate predict function).
- **Response variable** Type the name of the response variable, or select and double-click from the list that is provided. This variable will be displayed on the left-hand side of the formula (variable >0 ~) and is also the response variable that is plotted in the various result plots. The variable is selected as one of the variables (species) of the community dataset, it will be transformed to presence-absence and is first added to the environmental dataset. When you select the environmental dataset to be the community dataset as well, then you can select variables of the environmental dataset as response variable.

• Explanatory Type the right-hand side of the model formula (~ explanatory), or select and double-click for variables and select and click for operators to construct the right-hand side of the model formula.

- Remove site with name The name of the site to be removed from the environmental dataset.
- **Plot options** The options provide various functions that can be used to plot regression results of the current model (shown on top of the window; should have been estimated first).

Option "tabular" chooses function plot to plot presence-absence of the response variable against the selected categorical variable (shown on the right).

Option "diagnostic plots" chooses functions plot.lm or gam.check to plot diagnostic plots. For regression trees and artificial neural networks, the predicted values are plotted against the original presence-absence information.

Option "levene test" chooses function levene.test and plots residuals of the selected categorical variable (shown on the right).

Option "term plot" chooses functions termplot or plot. gam to plot a termplot of the selected categorical variable (shown on the right).

Option "effect plot" chooses function effect to plot an effect plot of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables).

Option "qq plot" chooses function qq.plot to plot the residuals from the model.

Option "result plot (new)" chooses an appropriate predict function to plot a new plot of the model predictions for the selected variable (shown on the right).

Option "result plot (add)" chooses an appropriate predict function to add a new plot of the model predictions for the selected variable (shown on the right)

Option "result plot (interpolate)" chooses an appropriate predict function to add a new plot of the model predictions for the selected variable (shown on the right). This model is predicted from a new dataset that only contains 1000 interpolated values for the selected explanatory variable.

Option "cr plot" chooses function cr.plots to plot a component + residual plots of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables.)

Option "av plot" chooses function av.plots to plot added variable plots of the selected variable (shown on the right). (The menu option of the R-Commander of models > Graphs plots all the variables and has an option of identifying sites with the mouse.)

Option "influence plot" chooses function influence.plot to plot influence plots. (The menu option of the R-Commander of models > Graphs has an option of identifying sites with the mouse.)

Option "multcomp" chooses function glht to plot simultaneous confidence intervals of the selected categorical variable (shown on the right).

Option "rpart" chooses functions plot.rpart and text.rpart to plot a dendrogram for the regression tree result.

- Plot variable Variable of the environmental dataset that is used for some plotting functions.
- **OK** Fit the selected models.
- **Plot** Plot results for the model with name that appears on top. The model options need to apply to the model (e.g. if a GLM method was used to fit the model, this option should also be selected when plotting the results).
- Cancel Close the window and do not estimate new regression models.

Calculate distance matrix

This window calculates a distance matrix from the community dataset and provides the following options:

- Save result as The name for the new distance matrix that will be calculated after "OK" was clicked.
- Distance Ecological distance measure. Passed as argument for "method" for function vegdist.
- Make community dataset) Make the data frame derived from the new distance matrix the active community data set. This distance matrix can be used directly in the other menus for analysis of ecological distance after selecting the "as.dist" options of these windows.
- OK Calculate the distance matrix.
- Cancel Close the window and do not calculate a new distance matrix.

Unconstrained ordination

The window fits and plots unconstrained ordination models. The menu provides the following options:

- Save result as The name for the new object that will save the results from the unconstrained ordination model after "OK" was clicked, or the name of the object that will be plotted when Plot is clicked. In case that you saved a result earlier, then you can plot the result by typing in the name of previous result first in this box.
- Ordination method Select the method of ordination analysis.

Option "PCA" fits a Principal Components Analysis model with function rda.

Option "PCA (prcomp)" fits a Principal Components Analysis model with function prcomp.

Option "PCoA" fits a Principal Coordinates Analysis model with function cmdscale using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix).

Option "PCoA (Caillez)" fits a Principal Coordinates Analysis model with function cmdscale using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix) and setting add=T.

Option "CA" fits a Correspondence Analysis (Reciprocal Averaging) model with function cca. Option "DCA" fits a Detrended Correspondence Analysis model with function decorana.

Option "metaMDS" fits a Non-metric Multidimensional Scaling model with function metaMDS using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix).

Option "NMS (standard)" fits a Non-metric Multidimensional Scaling model with function NMSrandom using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix).

• **Distance** Select the distance measure for the PCoA and NMS methods (other methods have fixed intrinsic distance measures [Euclidean or chi] that can not be changed).

For the methods that provide ordinations based on a distance matrix (PCoA and NMSstandard): passed as argument for "method" for function vegdist that calculates the distance matrix first.

Passed as argument for "distance" for function metaMDS.

• **PCoA or NMS axes** Select the number of axes to feature in PCoA and NMS results. Passed as argument for "k" for functions cmdscale, metaMDS or NMSrandom.

- NMS permutation Select the number of permutations for the NMS results. The solution with the lowest stress after all permutations of random starting positions will be provided. Passed as argument for "trymax" for function metaMDS or argument for "perm" for function NMSrandom.
- **PCoA or NMS species** Fit species scores to PCoA and NMS results with function add. spec. scores. This function adds some other information for PCoA.
- **Model summary** Provide a summary of the ordination with functions summary.cca, summary.decorana orotherwise list the model object.
- **Scaling** Provide the scaling method. Passed as argument for "scaling" for functions summary.cca, summary.decorana or add.spec.scores.
- as.dist(Community) Treat the community dataset as a distance matrix. The community dataset will be used as a distance matrix (via as.dist) for unconstrained ordination methods that use a distance matrix as input (cmdscale and NMSrandom for ordination results and via ordicluster, lines.spantree, ordicluster2, ordinearest or distdisplayed for plotting options).
- **Plot method** The options provide various functions that can be used to plot ordination results, or to add information to ordination diagrams.

Option "plot" chooses function plot.cca to plot results from rda, cca, metaMDS or decorana and function plot to plot the other ordination results (obtained by function scores).

Option "ordiplot" chooses function ordiplot to plot ordination results.

Option "ordiplot empty" chooses function ordiplot to plot ordination results, but sites and species will be invisible.

Option "identify sites" chooses function identify.ordiplot to add names of sites to site symbols (circles) created by function ordiplot. You can choose where the name is added by left-clicking in the quadrant next to the symbol where you want to symbol to be plotted. You can stop identifying sites by right-clicking.

Option "identify species" chooses function identify.ordiplot to add names of species to species symbols (crosses) created by function ordiplot. You can choose where the name is added by left-clicking in the quadrant next to the symbol where you want to symbol to be plotted. You can stop identifying species by right-clicking.

Option "text sites" chooses function text.ordiplot to add names of all sites to ordination diagrams created by function ordiplot.

Option "text species" chooses function text.ordiplot to add names of all species to ordination diagrams created by function ordiplot.

Option "points sites" chooses function points.ordiplot to add symbols for all sites to ordination diagrams created by function ordiplot.

Option "points species" chooses function points.ordiplot to add symbols for all species to ordination diagrams created by function ordiplot.

Option "origin axes" adds a horizontal and vertical line through the origin of the ordination graph (the origin is the location with coordinates [0,0]).

Option "envfit" chooses function envfit to add information for the variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordihull" chooses function ordihull to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordiarrows" chooses function ordiarrows to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisegments" chooses function ordisegments to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordispider" chooses function ordispider to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordiellipse" chooses function ordiellipse to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisurf" chooses function ordisurf to add information for the continuous variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordicluster" chooses function ordicluster to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix.) to ordination diagrams created by function ordiplot.

Option "ordispantree" chooses function lines.spantree to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordibubble" chooses function ordibubble to add information for the continuous variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisymbol" chooses function ordisymbol to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot. Make sure that you click in the graph to show where the legend should be placed!

Option "ordivector" chooses function ordivector to add information on the selected species of the community dataset selected on the right-hand side to ordination diagrams created by function ordiplot. You should first make the community dataset the environmental datset to get the list of species on the right-hand side.

Option "ordivector interpretation" chooses function ordivector to add information on the selected species of the community dataset selected on the right-hand side to ordination diagrams created by function ordiplot. You should first make the community dataset the environmental datset to get the list of specie son the right-hand side. The function will drop down perpendicular lines from each site to the line connecting the origin and the species position.

Option "ordicluster2" chooses function ordicluster2 to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordinearest" chooses function ordinearest to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordiequilibriumcircle" chooses function ordiequilibriumcircle to plot an equilibrium circle to ordination diagrams created by function ordiplot from the Principal Components Analysis fitted by rda.

Option "distance displayed" compares the distances between each pair of sites in a distance matrix (with distance measure selected in window above) with distances in ordination diagrams created by function ordiplot by means of function distdisplayed.

Option "screeplot.cca" provides a screeplot for PCA results obtained by function rda by means of function screeplot.cca.

Option "stress" provides a stress plot (Shepard diagram) for NMS results obtained by function metaMDS by means of function stressplot.

Option "coenocline" fits coenoclines for all species to the first ordination axis of ordination diagrams created by function ordiplot by means of function ordicoeno.

- Plot variable Variable of the environmental dataset that is used for some plotting functions. For Plot method "ordivector", make the community dataset the environmental dataset first. Some other plot methods may also work with the community dataset as the environmental dataset as well (e.g. "ordibubble", "ordisurf"). Some methods run into problems when the variable has missing observations: in this case, you may need to repeat the ordination analysis after removing sites with missing observations for the variable with the "remove NA" option of the Community dataset menu list.
- axes The position of the axes of the ordination result to be plotted in the ordination diagram ("1,2" selects the first two axes of the ordination result). Passed as argument for "choices" for functions plot.cca, scores or ordiplot.
- add scores to dataframe Adds the scores of the sites from the ordiplot graph to the environmental dataset using the model name combined with ".ax1" and ".ax2".
- cex The size of the characters in the resulting plot when "Plot" is clicked.
- colour The colour of the resulting plot when "Plot" is clicked.
- **OK** Fit the selected models.
- **Plot** Plot results for the model with name that appears on top. The model options need to apply to the model (e.g. if rda was used to fit the model, this option should also be selected when plotting the results).
- Cancel Close the window and do not fit or plot ordination models.

Constrained ordination

The window fits and plots constrained ordination models to the community dataset, using variables of the environmental dataset to contrain the ordination model (direct gradient analysis, canonical ordination analysis). The menu provides the following options:

- Save result as The name for the new object that will save the results from the unconstrained ordination model after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you can plot the result by typing in the name of previous result first in this box.
- Ordination method Select the method of ordination analysis.

Option "RDA" fits a Redundancy Analysis model with function rda.

Option "CCA" fits a Canonical Correspondence Analysis (Reciprocal Averaging) model with function cca.

Option "capscale" fits a scaled Constrained Analysis of Principal Coordinates (distance-based Redundancy Analysis) with function capscale using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix).

Option "CAPdiscrim" fits a Constrained Analysis of Principal Coordinates (based on discriminant analysis) with function CAPdiscrim using the distance measure selected on the right-hand side (except if the community matrix is interpreted as distance matrix) and the categorical variable selected as explanatory variable.

Option "prc" fits principal response curves with function prc. To implement the example provided in the documentation for the prc function, you need to include the additional steps of defining pyrifos.env <- data.frame(dose, week) and making this data set the environmental data set.

Option "multiconstrained (RDA)" provides the first row of all ANOVA results (anova.cca) for all possible pairwise combinations of the levels of the first explanatory variable (assumed to be a categorical variable) through function multiconstrained with method="rda". (When you change contrast to a particular contrast indicator, you obtain an ordination result that can be analyzed further. For several plotting options, you need to change the community and environmental datasets to "newcommunity" and "newenvdata").

Option "multiconstrained (CCA)" provides the first row of all ANOVA results (anova.cca) for all possible pairwise combinations of the levels of the first explanatory variable (assumed to be a categorical variable) through function multiconstrained with method="cca". (When you change contrast to a particular contrast indicator, you obtain an ordination result that can be analyzed further. For several plotting options, you need to change the community and environmental datasets to "newcommunity" and "newenvdata").

Option "multiconstrained (capscale)" provides the first row of all ANOVA results (anova.cca) for all possible pairwise combinations of the levels of the first explanatory variable (assumed to be a categorical variable) through function multiconstrained with method="capscale". (When you change contrast to a particular contrast indicator, you obtain an ordination result that can be analyzed further. For several plotting options, you need to change the community and environmental datasets to "newcommunity" and "newenvdata").

- **Distance** Select the distance measure for the CAP methods (other methods have fixed intrinsic distance measures [Euclidean or chi] that can not be changed). Passed as argument for "dist" for function capscale or CAPdiscrim. This argument is ignored by the actual functions if the community dataset is interpreted to be a distance matrix already.
- **Model summary** Provide a summary of the ordination with functions summary.cca or summary.prc,or otherwise list the model object (CAPdiscrim).
- as.dist(Community) Treat the community dataset as a distance matrix. The community dataset will be used as a distance matrix (via as.dist) for constrained ordination methods that can use a distance matrix as input (capscale or CAPdiscrim for ordination results and via ordicluster, lines.spantree, ordicluster2, ordinearest or distdisplayed for plotting options).
- **Scaling** Provide the scaling method. This option is not available for function CAPdiscrim. Passed as argument for "scaling" for function summary.cca or summary.prc.
- **permutations** Select the number of permutations for testing the significance of the constrained ordination by Monte-Carlo randomization tests. The default of "0" means that no permutation test will be done. Passed as argument for "permutations" for functions permutest.cca, CAPdiscrim or envfit (one of the plotting options) or as argument for "step" for function anova.cca (which is also called by multiconstrained).

• Explanatory Type the right-hand side of the model formula (~ explanatory), or select and double-click for variables and select and click for operators to construct the right-hand side of the model formula. It is possible to include conditional variables for partial ordination analysis, except for function CAPdiscrim and prc. For function prc, the explanatory variables should be separated by a comma and indicate the "treatment" and "time" factors.

• **Plot method** The options provide various functions that can be used to plot ordination results, or to add information to ordination diagrams.

Option "plot" chooses function plot.cca to plot results from rda, cca or capscale, function plot.prc to plot results from prc and function plot to plot the other ordination results (obtained by function scores).

Option "ordiplot" chooses function ordiplot to plot ordination results.

Option "ordiplot empty" chooses function ordiplot to plot ordination results, but sites and species will be invisible.

Option "identify sites" chooses function identify.ordiplot to add names of sites to site symbols (circles) created by function ordiplot. You can choose where the name is added by left-clicking in the quadrant next to the symbol where you want to symbol to be plotted. You can stop identifying sites by right-clicking.

Option "identify species" chooses function identify.ordiplot to add names of species to species symbols (crosses) created by function ordiplot. You can choose where the name is added by left-clicking in the quadrant next to the symbol where you want to symbol to be plotted. You can stop identifying species by right-clicking.

Option "identify centroids" chooses function identify.ordiplot to add names of centroids to centroid symbols (X) created by function ordiplot. You can choose where the name is added by left-clicking in the quadrant next to the symbol where you want to symbol to be plotted. You can stop identifying species by right-clicking.

Option "text sites" chooses function text.ordiplot to add names of all sites to ordination diagrams created by function ordiplot.

Option "text species" chooses function text.ordiplot to add names of all species to ordination diagrams created by function ordiplot.

Option "text centroids" chooses function text.ordiplot to add names of all centroids to ordination diagrams created by function ordiplot.

Option "points sites" chooses function points.ordiplot to add symbols for all sites to ordination diagrams created by function ordiplot.

Option "points species" chooses function points.ordiplot to add symbols for all species to ordination diagrams created by function ordiplot.

Option "points centroids" chooses function points.ordiplot to add symbols for all centroids to ordination diagrams created by function ordiplot.

Option "origin axes" adds a horizontal and vertical line through the origin of the ordination graph (the origin is the location with coordinates [0,0]).

Option "envfit" chooses function envfit to add information for the variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordihull" chooses function ordihull to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordiarrows" chooses function ordiarrows to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisegments" chooses function ordisegments to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordispider" chooses function ordispider to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordiellipse" chooses function ordiellipse to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisurf" chooses function ordisurf to add information for the continuous variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordicluster" chooses function ordicluster to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordispantree" chooses function lines.spantree to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordibubble" chooses function ordibubble to add information for the continuous variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot.

Option "ordisymbol" chooses function ordisymbol to add information for the categorical variable of the environmental dataset selected on the right-hand side to ordination diagrams created by function ordiplot. Make sure that you click in the graph to show where the legend should be placed!

Option "ordivector" chooses function ordivector to add information on the selected species of the community dataset selected on the right-hand side to ordination diagrams created by function ordiplot. You should first make the community dataset the environmental datset to get the list of species on the right-hand side.

Option "ordivector interpretation" chooses function ordivector to add information on the selected species of the community dataset selected on the right-hand side to ordination diagrams created by function ordiplot. You should first make the community dataset the environmental datset to get the list of specie son the right-hand side. The function will drop down perpendicular lines from each site to the line connecting the origin and the species position.

Option "ordicluster2" chooses function ordicluster2 to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "ordinearest" chooses function ordinearest to add information (with distance measure selected in window above - except if the community matrix is interpreted as distance matrix) to ordination diagrams created by function ordiplot.

Option "distance displayed" compares the distances between each pair of sites in a distance matrix (with distance measure selected in window above) with distances in ordination diagrams created by function ordiplot by means of function distdisplayed.

Option "coenocline" fits coenoclines for all species to the first ordination axis of ordination diagrams created by function ordiplot by means of function ordicoeno.

- Plot variable Variable of the environmental dataset that is used for some plotting functions. For Plot method "ordivector", make the community dataset the environmental dataset first. Some other plot methods may also work with the community dataset as the environmental dataset as well (e.g. "ordibubble", "ordisurf"). Some methods run into problems when the variable has missing observations: in this case, you may need to repeat the ordination analysis after removing sites with missing observations for the variable with the "remove NA" option of the Community dataset menu list.
- axes The position of the axes of the ordination result to be plotted in the ordination diagram ("1,2" selects the first two axes of the ordination result). Passed as argument for "choices" for functions plot.cca, scores or ordiplot.
- add scores to dataframe Adds the scores of the sites from the ordiplot graph to the environmental dataset using the model name combined with ".ax1" and ".ax2".
- cex The size of the characters in the resulting plot when "Plot" is clicked.
- **colour** The colour of the resulting plot when "Plot" is clicked.
- **OK** Fit the selected models.
- Plot Plot results for the model with name that appears on top. The model options need to apply to the model (e.g. if rda was used to fit the model, this option should also be selected when plotting the results).
- Cancel Close the window and do not fit or plot ordination models.

Clustering

This window performs various methods of cluster analysis based on the information of the community dataset. The menu provides the following options:

- Save cluster as The name for the new object that will save the results from the cluster analysis after "OK" was clicked, or the name of the object that will be plotted when "Plot" is clicked. In case that you saved a result earlier, then you can plot the result by typing in the name of previous result first in this box.
- Cluster method Select the method of ordination analysis.

Option "hclust" results in a cluster analysis fitted by function hclust. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

Option "agnes" results in a cluster analysis fitted by function agnes. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

Option "diana" results in a cluster analysis fitted by function diana. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

Option "kmeans" results in a cluster analysis fitted by function kmeans. This method is based on the Euclidean distance.

Option "cascadeKM" results in a cluster analysis fitted by function cascadeKM. This method is based on the Euclidean distance as it is based on K-means clustering.

Option "pam" results in a cluster analysis fitted by function pam. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

Option "clara" results in a cluster analysis fitted by function clara. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

Option "fanny" results in a cluster analysis fitted by function fanny. The distance for the distance matrix derived from the community dataset is selected on the right-hand side.

- **Distance** Ecological distance measure used for the distance matrix. Passed as argument for "method" for function vegdist.
- as.dist(Community) Treat the community dataset as a distance matrix. The community dataset will be used as a distance matrix (via as.dist). This option is not available for kmeans).
- **cluster summary** Provide the results of the cluster analysis with summary.agnes, summary.diana, summary.pam, summary.clara or summary.fanny or provide results of hclust or kmeans
- **cophenetic correlation** Calculate the correlation of the distances in the distance matrix with the distances in the dendrogram (estimated with function cophenetic) by the Mantel test (mantel). It only works for hierarchical clustering methods (hclust, agnes and diana).
- clusters Determine a fixed number of clusters.

This number selects the number of clusters to be calculated by the non-hierarchical cluster methods as it is passed as argument for "centers" for function kmeans and argument for "k" for functions pam, clara and fanny.

This number selects the number of groups for the partition with the largest number of groups of the cascade as it is passed as argument for "sup.gr" for function cascadeKM (the argument for "inf.gr" is set to "2").

This number selects the number of clusters to be reported for cluster membership for hierarchical clustering methods (hclust, agnes and diana) as determined by function cutree: passed as argument for "k" for this function.

This number selects the number of rectangles to be plotted on a dendrogram with plotting option of "rectangles": passed as argument for "k" for function rect.hclust.

This number selects the number of clusters to be plotted with plotting option of "pruned dendrogram": passed as argument for "k" for function clip.clust.

- Save cluster membership Save the identity of the cluster to which each site belongs into the environmental data set. For hierarchical clustering methods (hclust, agnes and diana) as determined by function cutree, with parameter "k" obtained from the box above.
- **Cluster options** Choose the options that are available for some of the hierarchical clustering methods.

Options "average", "single", "complete", "ward", "median" and "centroid" can be passed meaningfully as argument for "method" for hclust.

Options "average", "single", "complete", "ward" and "weighted" can be passed meaningfully as argument for "method" for agnes.

• **Plot options** Choose the options that are available for plotting hierarchical clustering results (except for "cascadeKM").

Option "dendrogram1" selects function plot.hclust, plot.agnes or plot.diana to plot clustering results.

Option "dendrogram2" selects function plot.hclust, plot.agnes or plot.diana to plot clustering results with argument hang set to -1. This option will result in each branch of the dendrogram to reach "ground level".

Option "rectangles" selects function rect.hclust to plot rectangles around the number of cluster determined by option "clusters" selected above.

Option "pruned dendrogram" selects function clip.clust to prune the cluster to the number of cluster selected by option "clusters" selected above. This option may only work with cluster results obtained by plot.hclust.

Option "kgs" selects function kgs as one method of selecting the optimal number of clusters and plots its results.

Option "cophenetic" uses function cophenetic to the distance in the dendrogram against the distance of the distance matrix (calculated earlier for the clustering algorithm). A reference line (y=x) is added to the graph.

Option "cascadeKM" selects function plot.cascadeKM to plot resuls obtained by function cascadeKM.

- cex The size of the characters in the resulting plot when "Plot" is clicked.
- colour The colour of the resulting plot when "Plot" is clicked.
- **OK** Fit the selected models.
- **Plot** Plot results for the cluster with name that appears on top. Plotting will only be meaningfull for hierarchical methods (hclust, agnes and diana).
- Cancel Close the window and do not analyse or plot clusters..

Compare distance matrices

This window calculates a distance matrix from the community dataset. This distance matrix can be analysed by a Mantel, MRPP or ANOSIM test based on information from the environmental dataset. You can compare two different community datasets if you make one the community dataset and the other one the environmental dataset. The menu provides the following options:

• **Type of test** Selects the type of test to be used.

Option "mantel" results in a Mantel test estimated by function mantel. The distance for distance matrix derived from the community dataset is selected below, the distance to be derived from the environmental dataset is selected on the right-hand side.

Option "anosim" results in a ANOSIM test estimated by function anosim as summarized by summary.anosim. The distance measure for the distance matrix derived from the community dataset is selected below, the categorical variable of the environmental dataset is selected at the right-hand side.

Option "mrpp" results in a MRPP test estimated by function mrpp. The distance measure for the distance matrix derived from the community dataset is selected below, the categorical variable of the environmental dataset is selected at the right-hand side.

Option "rankindex" results in a series of Mantel tests with a series of distance measures selected by function rankindex for the community dataset and the Euclidean distance for the environmental dataset (except for datasets that contain factors where daisy is used).

• Environmental distance The environmental distance is only used for the test option of "mantel" (test option of "rank index" makes its own choice in between "daisy" or "euclidean" distance). The distance determines the type of distance matrix that is obtained from the environmental data set.

Option "daisy" results in function daisy to be used for providing the distance matrix. This is the only realistic method for environmental datasets that contain categorical variables.

The other options are passed as arguments for "method" for function vegdist.

• **Community distance** Ecological distance measure used for the distance matrix obtained from the community data set.

Passed as argument for "method" for function vegdist.

For the "rankindex" type of test, a series of distance measures are tested automatically.

• Environmental variable Selection of the environmental variable(s). Some methods run into problems when the variable has missing observations: in this case, you may need to repeat the ordination analysis after removing sites with missing observations for the variable with the "remove NA" option of the Community dataset menu list.

For test option "mantel", when "all" is selected, then the distance matrix is calculated for all variables of the environmental dataset. For environmental datasets with some categorical variables, only environmental distance "daisy" will result in actual distance matrices.

For test option "mantel", when a variable is selected, then the distance matrix is only calculated for that variable. In case that the variable is categorical, then the daisy distance is used automatically.

For test option "anosim", the selected environmental variable is passed as argument for "grouping" for function anosim.

For test option "mrpp", the selected environmental variable is passed as argument for "grouping" for function mrpp.

For test option "rankindex", when "all" is selected, then the environmental dataset is passed as argument for "grad" for function rankindex.

For test option "rankindex", the selected variable is passed as argument for "grad" for function rankindex.

- as.dist(Community) Treat the community dataset as a distance matrix. The community dataset will be used as a distance matrix (via as.dist).
- Plot results Plots the distances of the community dataset against the distance of the environmental dataset for test options "mantel", "anosim" and "mrpp". For categorical variables (the only possibility for "anosim" and "mrpp"), environmental distance equals "0" if sites belong to the same group and "1" if they belong to a different group except if they are ordered categorical variables (depending on the results of the daisy distance; for ordered factors, it is recommended to create a new factor that is unordered and use this variable for the analysis; see factor).
- **permutations** Number of permutations. Passed as argument for "permutations" for functions mantel, anosim and mrpp.
- correlation Correlation method. Passed as argument for "method" for function mantel.
- **OK** Estimate the selected tests.
- Cancel Close the window and do estimate a new test.

CAPdiscrim	Canonical Analysis of Principal Coordinates based on Discriminant Analysis

Description

This function provides a method for CAP as described by the authors of the ordination method. The CAP method implemented in **vegan** through capscale conforms more to distance-based Redundancy Analysis (Legendre & Anderson, 1999) than to the original description for CAP (Anderson & Willis, 2003).

Usage

CAPdiscrim(formula, data, dist="bray", axes=4, m=0, permutations=0)

Arguments

formula	Formula with a community data frame (with sites as rows, species as columns and species abundance as cell values) or distance matrix on the left-hand side and a categorical variable on the right-hand side (only the first explanatory variable will be used).
data	Environmental data set.
dist	Method for calculating ecological distance with function vegdist: partial match to "manhattan", "euclidean", "canberra", "bray", "kulczynski", "jaccard", "gower", "morisita", "horn" or "mountford". This argument is ignored in case that the left-hand side of the formula already is a distance matrix.
axes	Number of PCoA axes (cmdscale) to provide in the result.
m	Number of PCoA axes to be investigated by discriminant analysis (1da). If m=0 then the number of axes that provides the best distinction between the groups is calculated (following the method of Anderson and Willis).
permutations	The number of permutations for significance testing.

Details

This function provides a method of Constrained Analysis of Principal Coordinates (CAP) that conforms to the description of the method by the developers of the method, Anderson and Willis. The method investigates the results of a Principal Coordinates Analysis (function cmdscale) with linear discriminant analysis (lda). Anderson and Willis advocate to use the number of principal coordinate axes that result in the best prediction of group identities of the sites.

For permutations > 0, the analysis is repeated by randomising the observations of the environmental data set. The significance is estimated by dividing the number of times the randomisation generated a larger percentage of correct predictions.

34 CAPdiscrim

Value

The function returns an object with information on CAP based on discriminant analysis. The object contains following elements:

PCoA the positions of the sites as fitted by PCoA

m the number of axes analysed by discriminant analysis
tot the total variance (sum of all eigenvalues of PCoA)
varm the variance of the m axes that were investigated

group the original group of the sites

CV the predicted group for the sites by discriminant analysis

percent the percentage of correct predictions

x the positions of the sites provided by the discriminant analysis

F the squares of the singulare values of the discriminant analysis

manova the results for MANOVA with the same grouping variable

signi the significance of the percentage of correct predictions

a summary of the observed randomised prediction percentages

The object can be plotted with ordiplot, and species scores can be added by add. spec. scores.

Examples

caprescale 35

caprescale	Rescaling of Capscale Results to Reflect Total Sums of Squares Of Distance Matrix

Description

This is a simple function that rescales the ordination coordinates obtained from the distance-based redundancy analysis method implemented in **vegan** through capscale. The rescaling of the ordination coordinates results in the distances between fitted site scores in ordination results (scaling=1 obtained via ordiplot to be equal to the distances between sites on the axes corresponding to positive eigenvalues obtained from principal coordinates analysis (cmdscale).

Usage

caprescale(x,verbose=FALSE)

Arguments

x Ordination result obtained with capscale.

verbose Give some information on the pairwise distances among sites (TRUE) or not.

Details

The first step of distance-based redundancy analysis involves principal coordinates analysis whereby the distances among sites from a distance matrix are approximated by distances among sites in a multidimensional configuration (ordination). In case that the principal coordinates analysis does not result in negative eigenvalues, then the distances from the distance matrix are the same as the distances among the sites in the ordination. In case that the principal coordinates analysis results in negative eigenvalues, then the distances among the sites on all ordination axes are related to the sum of positive eigenvalues, a sum which is larger than the sum of squared distances of the distance matrix.

The distance-based redundancy analysis method implemented in **vegan** through capscale uses a specific rescaling method for ordination results. Function caprescale modifies the results of capscale so that an ordination with scaling=1 (a distance biplot) obtained viaordiplot preserves the distances reflected in the principal coordinates analysis implemented as the first step of the analysis. See Legendre and Legendre (1998) about the relationship between fitted site scores and eigenvalues.

Value

The function modifies and returns an object obtained via capscale.

crosstabanalysis

Presence-absence Analysis by Cross Tabulation

Description

This function makes a cross-tabulation of two variables after transforming the first variable to presence-absence and then returns results of chisq.test.

Usage

```
crosstabanalysis(x,variable,factor)
```

deviancepercentage 37

Arguments

	D				1 11 0 . 11
V	Liata cot tha	t containe the	Variables	"voriable"	and "factor".
Λ	Data set ma	t contains the	variables	variabic	and factor.

variable Variable to be transformed in presence-absence in the resulting cross-tabulation.

factor Variable to be used for the cross-tabulation together with the transformed vari-

able.

Value

The function returns the results of chisq.test on a crosstabulation of two variables, after transforming the first variable to presence-absence first.

deviancepercentage $\it Calculate Percentage and Significance of Deviance Explained by a \it GLM$

Description

This function calculates the percentage of deviance explained by a GLM model and calculates the significance of the model.

Usage

```
deviancepercentage(x,data,test="F",digits=2)
```

38 deviancepercentage

Arguments

X	Result of GLM as calculated by glm or glm.nb.
data	Data set to be used for the null model (preferably the same data set used by the 'full' model).
test	Test statistic to be used for the comparison between the null model and the 'full' model as estimated by anova.glm or anova.negbin: partial match of one of "Chisq", "F" or "Cp".
digits	Number of digits in the calculation of the percentage.

Details

The function calculates the percentage of explained deviance and the significance of the 'full' model by contrasting it with the null model.

For the null model, the data is subjected to na.omit. You should check whether the same data are used for the null and 'full' models.

Value

The function calculates the percentage of explained deviance and the significance of the 'full' model by contrasting it with the null model by ANOVA. The results of the ANOVA are also provided.

Examples

dist.eval 39

|--|

Description

Function dist.eval provides one test of a distance matrix, and then continues with distconnected (**vegan**). Function prepare.bioenv converts selected variables to numeric variables and then excludes all categorical variables in preparation of applying bioenv (**vegan**).

Usage

```
dist.eval(x, dist)
prepare.bioenv(env, as.numeric = c())
```

Arguments

х	Community data frame with sites as rows, species as columns and species abundance as cell values.
env	Environmental data frame with sites as rows and variables as columns.
dist	Method for calculating ecological distance with function <code>vegdist</code> : partial match to "manhattan", "euclidean", "canberra", "bray", "kulczynski", "jaccard", "gower", "morisita", "horn" or "mountford".
as.numeric	Vector with names of variables in the environmental data set to be converted to numeric variables.

Details

Function dist.eval provides two tests of a distance matrix:

- (i) The first test checks whether any pair of sites that share some species have a larger distance than any other pair of sites that do not share any species. In case that cases are found, then a warning message is given.
- (ii) The second test is the one implemented by the distconnected function (vegan). The distconnected test is only calculated for distances that calculate a value of 1 if sites share no species (i.e. not manhattan or euclidean), using the threshold of 1 as an indication that the sites do not share any species. Interpretation of analysis of distance matrices that provided these warnings should be cautious.

Function prepare.bioenv provides some simple methods of dealing with categorical variables prior to applying bioenv.

Value

The function tests whether distance matrices have some desirable properties and provide warnings if this is not the case.

```

dist.zeroes

Distance Matrix Transformation

Description

Sample units without any species result in "NaN" values in the distance matrix for some of the methods of vegdist (vegan). The function replaces "NA" by "0" if both sample units do not contain any species and "NA" by "1" if only one sample unit does not have any species.

Usage

```
dist.zeroes(comm, dist)
```

Arguments

comm	Community data frame	with sites as rows, spe	ecies as columns and	d species abun-

dance as cell values.

dist Distance matrix as calculated with function vegdist.

distdisplayed 41

Details

This functions changes a distance matrix by replacing "NaN" values by "0" if both sample units do not contain any species and by "1" if only one sample unit does not contain any species.

Please note that there is a valid reason (deliberate removal of zero abundance values from calculations) that the original distance matrix contains "NaN", so you may not wish to do this transformation and remove sample units with zero abundances from further analysis.

Value

The function provides a new distance matrix where "NaN" values have been replaced by "0" or "1".

distdisplayed

Compare Distance Displayed in Ordination Diagram with Distances of Distance Matrix

Description

This function compares the distance among sites as displayed in an ordination diagram (generated by ordiplot) with the actual distances among sites as available from a distance matrix (as generated by vegdist).

Usage

```
distdisplayed(x, ordiplot, distx = "bray", plotit = T, addit = F,
    method = "spearman", permutations = 100, abline = F, gam = T, ...)
```

42 distdisplayed

Arguments

X	Community data frame (with sites as rows, species as columns and species abundance as cell values) or distance matrix.
ordiplot	Ordination diagram generated by ordiplot or distance matrix.
distx	Ecological distance used to calculated the distance matrix (theoretically the same distance as displayed in the ordination diagram); passed to vegdist and partial match to "manhattan", "euclidean", "canberra", "bray", "kulczynski", "jaccard", "gower", "morisita", "horn", "mountford", "raup" , "binomial" or "chao". This argument is ignored in case that "x" is already a distance matrix.
plotit	Should a plot comparing the distance in ordination diagram (or the distance matrix) with the distance from the distance matrix be generated (or not).
addit	Should the GAM regression result be added to an existing plot (or not).
method	Method for calculating the correlation between the ordination distance and the complete distance; from function mantel passed to function cor: "pearson", "spearman" or "kendall".
permutations	Number of permutations to assess the significance of the Mantel test; passed to mantel.
abline	Should a reference line (y=x) be added to the graph (or not).
gam	Evaluate the correspondence between the original distance and the distance from the ordination diagram with GAMas estimated by gam.
	Other arguments passed to mantel.

Details

This function compares the Euclidean distances (between sites) displayed in an ordination diagram with the distances of a distance matrix. Alternatively, the distances of one distance matrix are compared against the distances of another distance matrix.

These distances are compared by a Mantel test (mantel) and (optionally) a GAM regression (gam). Optionally, a graph is provided compairing the distances and adding GAM results. .

Value

The function returns the results of a Mantel test and (optionally) the results of a GAM analysis.

distransform 43

Examples

disttransform

Community Matrix Transformation

Description

Transforms a community matrix. Some transformation methods are described by distances for the original community matrix that result in the same distance matrix as calculated with the euclidean distance from the transformed community matrix. In several cases (methods of "hellinger", "chord", "profiles" and "chi.square), the method makes use of function decostand. In several other cases ("Braun.Blanquet", "Domin", "Hult", "Hill", "fix" and "coverscale.log"), the method makes use of function coverscale.

Usage

```
disttransform(x, method="hellinger")
```

Arguments

x Community data frame with sites as rows, species as columns and species abun-

dance as cell values.

method Distance measure for the original community matrix that the euclidean dis-

tance will calculate for the transformed community matrix: partial match to "hellinger", "chord", "profiles", "chi.square", "log", "square", "pa", "Braun.Blanquet",

"Domin", "Hult", "Hill", "fix" and "coverscale.log".

Details

This functions transforms a community matrix.

Some transformation methods ("hellinger", "chord", "profiles" and "chi.square") have the behaviour that the euclidean distance from the transformed matrix will equal a distance of choice for the original matrix. For example, using method "hellinger" and calculating the euclidean distance will result in the same distance matrix as by calculating the Hellinger distance from the original community matrix.

Transformation methods ("Braun.Blanquet", "Domin", "Hult", "Hill", "fix" and "coverscale.log") call function coverscale.

44 diversityresult

Value

The function returns a transformed community matrix.

diversityresult

Alternative Diversity Results

Description

Provides alternative methods of obtaining results on diversity statistics than provided directly by functions diversity, fisher.alpha, specpool and specnumber (all from vegan), although these same functions are called. Some other statistics are also calculated such as the reciprocal Berger-Parker diversity index and abundance (not a diversity statistic). The statistics can be calculated for the entire community, for each site separately, the mean of the sites can be calculated or a jackknife estimate can be calculated for the community.

Usage

diversity result 45

Arguments

x Community data frame with sites as rows, species as columns and species abundance as cell values.

y Environmental data frame.

factor Variable of the environmental data frame that defines subsets to calculate diver-

sity statistics for.

level Level of the variable to create the subset to calculate diversity statistics.

index Type of diversity statistic with "richness" to calculate species richness, "abun-

dance" to calculate abundance, "Shannon" to calculate the Shannon diversity index, "Simpson" to calculate 1-Simpson concentration index, "inverseSimpson" to calculate the reciprocal Simpson diversity index, "Logalpha" to calculate the log series alpha diversity index, "Berger" to calculate the reciprocal Berger-Parker diversity index, "Jevenness" to calculate one Shannon evenness index, "Eevenness" to calculate another Shannon evenness index, "jack1" to calculate the first-order jackknife gamma diversity estimator, "jack2" to calculate the second-order jackknife gamma diversity estimator, "chao" to calculate the Chao gamma diversity estimator and "boot" to calculate the bootstrap gamma

diversity estimator.

method Method of calculating the diversity statistics: "all" calculates the diversity of

the entire community (all sites pooled), "s" calculates the diversity of each site separatedly, "mean" calculates the average diversity of the sites, "sd" calculates the standard deviation of the diversity of the sites, whereas "jackknife" calculates the jackknifed diversity for the entire data frame. Method "s" is not allowed for

diversitycomp.

sortit Sort the sites by increasing values of the diversity statistic.

digits Number of digits in the results.

factor1 Variable of the environmental data frame that defines subsets to calculate diver-

sity statistics for.

factor2 Optional second variable of the environmental data frame that defines subsets

to calculate diversity statistics for in a crosstabulation with the other variable of

the environmental data frame.

... Other arguments passed to function diversityresult.

Details

These functions provide some alternative methods of obtaining results with diversity statistics, although functions diversity, fisher.alpha, specpool, estimateR and specnumber (all from **vegan**) are called to calculate the various statistics.

The reciprocal Berger-Parker diversity index is the reciprocal of the proportional abundance of the most dominant species.

J-evenness is calculated as: H / ln(S) where H is the Shannon diversity index and S the species richness.

E-evenness is calculated as: exp(H) / S where H is the Shannon diversity index and S the species richness.

The method of calculating the diversity statistics include following options: "all" calculates the diversity of the entire community (all sites pooled together), "s" calculates the diversity of each site separatedly, "mean" calculates the average diversity of the sites, whereas "Jackknife" calculates the jackknifed diversity for the entire data frame. Methods "s" and "mean" are not available for function diversity comp. Gamma diversity estimators assume that the method is "all".

Functions diversityresult and diversitycomp allow to calculate diversity statistics for subsets of the community and environmental data sets. Function diversityresult calculates the diversity statistics for the specified level of a selected environmental variable. Function diversitycomp calculates the diversity statistics for all levels of a selected environmental variable separatedly. When a second environmental variable is provided, function diversitycomp calculates diversity statistics as a crosstabulation of both variables.

Value

The functions provide alternative methods of obtaining diversity results. For function diversitycomp, the number of sites is provided as "n".

ensemble.batch

Suitability mapping based on ensembles of modelling algorithms: batch processing

Description

The main function allows for batch processing of different species and different environmental RasterStacks. The function makes internal calls to ensemble.test.splits, ensemble.test and ensemble.raster.

Usage

```
ensemble.batch(x = NULL, xn = c(x), ext = NULL,
   species.presence = NULL, species.absence = NULL,
   presence.min = 20,
   an = 1000, excludep = FALSE,
   k.splits = 5, k.test = 0,
   n.ensembles = 1,
   SINK = FALSE,
   RASTER.format = "raster", RASTER.datatype = "INT2S", RASTER.NAflag = -32767,
   KML.out = FALSE, KML.maxpixels = 100000, KML.blur = 10,
   models.save = FALSE,
    threshold.method = "spec_sens", threshold.sensitivity = 0.9,
   ENSEMBLE.best = 0, ENSEMBLE.min = 0.7, ENSEMBLE.exponent = 1,
    input.weights = NULL,

```

```
threshold = -1,
threshold.method = "spec_sens", threshold.sensitivity = 0.9)
```

Arguments

x RasterStack object (stack) containing all layers to calibrate an ensemble.

xn RasterStack object (stack) containing all layers that correspond to explanatory variables of an ensemble calibrated earlier with x. Several RasterStack objects

can be provided in a format as c(stack1, stack2, stack3); these will be used sequentially. See also predict.

ext an Extent object to limit the prediction to a sub-region of xn and the selection of

background points to a sub-region of x, typically provided as c(lonmin, lonmax,

latmin, latmax); see also predict, randomPoints and extent

species.presence

presence points used for calibrating the suitability models, available in 3-column

(species, x, y) or (species, lon, lat) dataframe

species.absence

background points used for calibrating the suitability models, either available in a 3-column (species, x, y) or (species, lon, lat), or available in a 2-column (x, y) or (lon, lat) dataframe. In case of a 2-column dataframe, the same background

locations will be used for all species.

presence.min minimum number of presence locations for the organism (if smaller, no models

are fitted).

an number of background points for calibration to be selected with randomPoints

in case argument a or species. absence is missing

excludep parameter that indicates (if TRUE) that presence points will be excluded from the

background points; see also randomPoints

k If larger than 1, the mumber of groups to split between calibration (k-1) and

evaluation (1) data sets (for example, k=5 results in 4/5 of presence and background points to be used for calibrating the models, and 1/5 of presence and

background points to be used for evaluating the models). See also kfold.

k.splits If larger than 1, the number of splits for the ensemble.test.splits step in

batch processing. See also kfold.

k.test If larger than 1, the mumber of groups to split between calibration (k-1) and

evaluation (1) data sets when calibrating the final models (for example, k=5 results in 4/5 of presence and background points to be used for calibrating the models, and 1/5 of presence and background points to be used for evaluating the

models). See also kfold.

n.ensembles If larger than 1, the number of different ensembles generated per species in batch

processing.

SINK Append the results to a text file in subfolder 'outputs' (if TRUE). The name of

file is based on species names. In case a file already exists, then results are

appended. See also sink.

RASTER. format Format of the raster files that will be generated. See writeFormats and writeRaster.

RASTER.datatype

Format of the raster files that will be generated. See dataType and writeRaster.

RASTER.NAflag Value that is used to store missing data. See writeRaster.

if FALSE, then no kml layers (layers that can be shown in Google Earth) are KML.out

produced. If TRUE, then kml files will be saved in a subfolder 'kml'.

Maximum number of pixels for the PNG image that will be displayed in Google KML.maxpixels

Earth. See also KML.

KML.blur Integer that results in increasing the size of the PNG image by KML.blur^2,

which may help avoid blurring of isolated pixels. See also KML.

models.save Save the list with model details to a file (if TRUE). The filename will be species.name

with extension .models; this file will be saved in subfolder of models. When

loading this file, model results will be available as ensemble.models.

threshold.method

Method to calculate the threshold between predicted absence and presence; possibilities include spec_sens (highest sum of the true positive rate and the true negative rate), kappa (highest kappa value), no_omission (highest threshold that corresponds to no omission), prevalence (modeled prevalence is closest to observed prevalence) and equal_sens_spec (equal true positive rate and true negative rate). See threshold. Options specific to the BiodiversityR implementation are: threshold.mean (resulting in calculating the mean value of spec_sens, equal_sens_spec and prevalence) and threshold.min (resulting in calculating the minimum value of spec_sens, equal_sens_spec and

prevalence).

threshold.sensitivity

Sensitivity value for threshold.method = 'sensitivity'. See threshold.

ENSEMBLE.best The number of individual suitability models to be used in the consensus suitabil-

ity map (based on a weighted average). In case this parameter is smaller than 1 or larger than the number of positive input weights of individual models, then all individual suitability models with positive input weights are included in the

consensus suitability map.

ENSEMBLE.min The minimum input weight (assumed to correspond to evaluation indices of suit-

ability models) for a model to be included in the ensemble.

ENSEMBLE.exponent

Exponent applied to AUC values to convert AUC values into weights (for example, an exponent of 2 converts input weights of 0.7, 0.8 and 0.9 into 0.7²=0.49,

 $0.8^2=0.64$ and $0.9^2=0.81$). See ensemble.test for details.

input.weights array with numeric values for the different modelling algorithms; if NULL then

values provided by parameters such as MAXENT and GBM will be used. As an

alternative, the output from ensemble.test.splits can be used.

MAXENT Input weight for a maximum entropy model (maxent). (Only weights > 0 will

be used.)

GBM Input weight for a boosted regression trees model (gbm). (Only weights > 0 will

GBMSTEP Input weight for a stepwise boosted regression trees model (gbm. step). (Only

weights > 0 will be used.)

RF Input weight for a random forest model (randomForest). (Only weights > 0will be used.) GLM Input weight for a generalized linear model (glm). (Only weights > 0 will be used.) **GLMSTEP** Input weight for a stepwise generalized linear model (stepAIC). (Only weights > 0 will be used.) GAM Input weight for a generalized additive model (gam). (Only weights > 0 will be used.) **GAMSTEP** Input weight for a stepwise generalized additive model (step.gam). (Only weights > 0 will be used.) MGCV Input weight for a generalized additive model (gam). (Only weights > 0 will be used.) MGCVFIX number: if larger than 0, then a generalized additive model with fixed d.f. regression splines (gam) will be fitted among ensemble **EARTH** Input weight for a multivariate adaptive regression spline model (earth). (Only weights > 0 will be used.) **RPART** Input weight for a recursive partioning and regression tree model (rpart). (Only weights > 0 will be used.) **NNFT** Input weight for an artificial neural network model (nnet). (Only weights > 0 will be used.) FDA Input weight for a flexible discriminant analysis model (fda). (Only weights > 0 will be used.) SVM Input weight for a support vector machine model (ksvm). (Only weights > 0 will be used.) **SVME** Input weight for a support vector machine model (svm). (Only weights > 0 will be used.) **BIOCLIM** Input weight for the BIOCLIM algorithm (bioclim). (Only weights > 0 will be used.) Input weight for the DOMAIN algorithm (domain). (Only weights > 0 will be DOMAIN used.) MAHAL Input weight for the Mahalonobis algorithm (mahal). (Only weights > 0 will be used.) PROBIT If TRUE, then subsequently to the fitting of the individual algorithm (e.g. maximum entropy or GAM) a generalized linear model (glm) with probit link family=binomial(link="probined probined p will be fitted to transform the predictions, using the previous predictions as explanatory variable. This transformation results in all model predictions to be probability estimates. AUC.weights If TRUE, then use the average of the AUC for the different submodels in the different crossvalidation runs as weights for the 'full' ensemble model. See ensemble.test.splits for details. Yweights chooses how cases of presence and background (absence) are weighted; "BIOMOD" results in equal weighting of all presence and all background cases, "equal" re-

sults in equal weighting of all cases. The user can supply a vector of weights

similar to the number of cases in the calibration data set.

layer.drops vector that indicates which layers should be removed from RasterStack x. See

also addLayer.

factors vector that indicates which variables are factors; see also prepareData

dummy.vars vector that indicates which variables are dummy variables (influences formulae

suggestions)

formulae.defaults

Suggest formulae for most of the models (if TRUE). See also ensemble. formulae.

maxit Maximum number of iterations for some of the models. See also glm.control,

gam.control, gam.control and nnet.

MAXENT. a background points used for calibrating the maximum entropy model (maxent),

 $typically\ available\ in\ 2\text{-}column\ (lon,\ lat)\ data frame;\ see\ also\ prepareData\ and$

extract. Ignored if MAXENT. BackData is provided.

MAXENT. an number of background points for calibration to be selected with randomPoints

in case argument MAXENT.a is missing. When used with the ensemble.batch function, the same background locations will be used for each of the species runs; this implies that for each species, presence locations are not excluded from

the background data for this function.

MAXENT.BackData

dataframe containing explanatory variables for the background locations. This information will be used for calibrating the maximum entropy model (maxent). When used with the ensemble batch function, the same background locations will be used for each of the cross-validation runs; this is based on the assumption that a large number (~10000) of background locations are used.

that a range number (10000) or background locations are used.

MAXENT.path path to the directory where output files of the maximum entropy model are

stored; see also maxent

GBM. formula for the boosted regression trees algorithm; see also gbm

GBM.n.trees total number of trees to fit for the boosted regression trees model; see also gbm

GBMSTEP.gbm.x indices of column numbers with explanatory variables for stepwise boosted re-

gression trees; see also gbm. step

GBMSTEP.tree.complexity

complexity of individual trees for stepwise boosted regression trees; see also

gbm.step

GBMSTEP.learning.rate

weight applied to individual trees for stepwise boosted regression trees; see also

gbm.step

GBMSTEP.bag.fraction

proportion of observations used in selecting variables for stepwise boosted re-

gression trees; see also gbm.step

GBMSTEP.step.size

number of trees to add at each cycle for stepwise boosted regression trees (should be small enough to result in a smaller holdout deviance than the initial number

of trees [50]); see also gbm. step

RF. formula for the random forest algorithm; see also randomForest

RF.ntree number of trees to grow for random forest algorithm; see also randomForest

RF.mtry	number of variables randomly sampled as candidates at each split for random forest algorithm; see also randomForest
GLM.formula	formula for the generalized linear model; see also glm
GLM.family	description of the error distribution and link function for the generalized linear model; see also ${\tt glm}$
GLMSTEP.steps	maximum number of steps to be considered for stepwise generalized linear model; see also stepAIC
STEP.formula	formula for the "starting model" to be considered for stepwise generalized linear model; see also stepAIC
GLMSTEP.scope	range of models examined in the stepwise search; see also stepAIC
GLMSTEP.k	multiple of the number of degrees of freedom used for the penalty (only $k=2$ gives the genuine AIC); see also stepAIC
GAM.formula	formula for the generalized additive model; see also gam
GAM.family	description of the error distribution and link function for the generalized additive model; see also gam
GAMSTEP.steps	maximum number of steps to be considered in the stepwise generalized additive model; see also step.gam
GAMSTEP.scope	range of models examined in the step-wise search n the stepwise generalized additive model; see also step.gam
GAMSTEP.pos	parameter expected to be set to 1 to allow for fitting of the stepwise generalized additive model
MGCV.formula	formula for the generalized additive model; see also gam
MGCV.select	if TRUE, then the smoothing parameter estimation that is part of fitting can completely remove terms from the model; see also gam
MGCVFIX.formula	
	formula for the generalized additive model with fixed d.f. regression splines; see also gam (the default formulae sets "s(, fx=TRUE,)"; see also s)
EARTH.formula	formula for the multivariate adaptive regression spline model; see also earth
EARTH.glm	list of arguments to pass on to glm; see also earth
RPART.formula	formula for the recursive partioning and regression tree model; see also rpart
RPART.xval	number of cross-validations for the recursive partioning and regression tree model; see also ${\tt rpart.control}$
NNET.formula	formula for the artificial neural network model; see also nnet
NNET.size	number of units in the hidden layer for the artificial neural network model; see also nnet
NNET.decay	parameter of weight decay for the artificial neural network model; see also nnet
FDA.formula	formula for the flexible discriminant analysis model; see also fda
SVM.formula	formula for the support vector machine model; see also ksvm
SVME.formula	formula for the support vector machine model; see also svm
MAHAL.shape	parameter that influences the transformation of output values of mahal. See details section.

RASTER.species.name

First part of the names of the raster files, expected to identify the modelled species (or organism).

RASTER.stack.name

Last part of the names of the raster files, expected to identify the predictor stack used.

positive.filters

vector that indicates parts of filenames for files that will be included in the calculation of the mean probability values

negative.filters

vector that indicates parts of filenames for files that will not be included in the calculation of the mean probability values

p presence points used for calibrating the suitability models, typically available in 2-column (x, y) or (lon, lat) dataframe; see also prepareData and extract

background points used for calibrating the suitability models, typically available in 2-column (x, y) or (lon, lat) dataframe; see also prepareData and extract

pt presence points used for evaluating the suitability models, typically available in

2-column (lon, lat) dataframe; see also prepareData

at background points used for calibrating the suitability models, typicall available

in 2-column (lon, lat) dataframe; see also prepareData and extract

threshold Threshold value that will be used to distinguish between presence and absence.

If < 0, then a threshold value will be calculated from the provided presence p

and absence a locations.

Details

This function allows for batch processing of different species and different environmental Raster-Stacks. The function makes internal calls to ensemble.test.splits, ensemble.test and ensemble.raster.

ensemble.test.splits results in a cross-validation procedure whereby the data set is split in calibration and testing subsets and the best weights for the ensemble model are determined (including the possibility for weights = 0).

ensemble. test is the step whereby models are calibrated using all the available presence data.

ensemble.raster is the final step whereby raster layers are produced for the ensemble model.

Function ensemble.mean results in raster layers that are based on the summary of several ensemble layers: the new ensemble has probability values that are the mean of the probabilities of the different raster layers, the presence-absence threshold is derived for this new ensemble layer, whereas the count reflects the number of ensemble layers where presence was predicted. Note the assumption that input probabilities are scaled between 0 and 1000 (as the output from ensemble.raster), whereas thresholds are based on actual probabilities (scaled between 0 and 1).

Value

The function finally results in ensemble raster layers for each species, including the fitted values for the ensemble model, the estimated presence-absence and the count of the number of submodels prediction presence and absence.

ensemble.dummy.variables

Suitability mapping based on ensembles of modelling algorithms: handling of categorical data

Description

The basic function ensemble.dummy.variables creates new raster layers representing dummy variables (coded 0 or 1) for all or the most frequent levels of a caterogical variable. Sometimes the creation of dummy variables is needed for proper handling of categorical data for some of the suitability modelling algorithms.

Usage

```
ensemble.dummy.variables(xcat=NULL,
    freq.min=50, most.frequent=5,
    overwrite=TRUE, ...)
ensemble.accepted.categories(xcat = NULL, categories = NULL,
    filename=NULL, overwrite=TRUE, ...)
ensemble.simplified.categories(xcat = NULL, p = NULL,
    filename=NULL, overwrite=TRUE, ...)
```

Arguments

xcat

RasterLayer object (raster) containing values for a categorical explanatory variable.

freq.min	Minimum frequency for a dummy raster layer to be created for the corresponding factor level. See also freq.
most.frequent	Number of dummy raster layers to be created (if larger than 0), corresponding to the same number of most frequent factor levels See also freq.
overwrite	$overwrite\ an\ existing\ file\ name\ with\ the\ same\ name\ (if\ TRUE).\ See\ also\ \verb writeRaster .$
• • •	additional arguments for writeRaster or (for ensemble.dummy.variables, writeRaster).
categories	numeric vector providing the accepted levels of a categorical raster layer; expected to correspond to the levels encountered during calibration
filename	name for the output file. See also writeRaster.
p	presence points that will be used for calibrating the suitability models, typically available in 2-column (x, y) or (lon, lat) dataframe; see also prepareData and extract

Details

The basic function ensemble.dummy.variables creates dummy variables from a RasterLayer object (see raster) that represents a categorical variable. With freq.min and most.frequent it is possible to limit the number of dummy variables that will be created. For example, most.frequent = 5 results in five dummy variables to be created.

Function ensemble.accepted.categories modifies the RasterLayer object (see raster) by replacing cell values for categories (levels) that are not accepted with missing values.

Function ensemble.simplified.categories modifies the RasterLayer object (see raster) by replacing cell values for categories (levels) where none of the presence points occur with the same level. This new level is coded by the maximum coding level for these 'outside categories'.

Value

The basic function ensemble.raster mainly results in the creation of raster layers that correspond to dummy variables.

ensemble.raster

Suitability mapping based on ensembles of modelling algorithms: consensus mapping

Description

The basic function ensemble.raster creates two consensus raster layers, one based on a (weighted) average of different suitability modelling algorithms, and a second one documenting the number of modelling algorithms that predict presence of the focal organisms. Modelling algorithms include maximum entropy (MAXENT), boosted regression trees, random forests, generalized linear models (including stepwise selection of explanatory variables), generalized additive models (including stepwise selection of explanatory variables), multivariate adaptive regression splines, regression trees, artificial neural networks, flexible discriminant analysis, support vector machines, the BIO-CLIM algorithm, the DOMAIN algorithm and the Mahalonobis algorithm. These sets of functions were developed in parallel with the biomod2 package, especially for inclusion of the maximum entropy algorithm, but also to allow for a more direct integration with the BiodiversityR package, more direct handling of model formulae and greater focus on mapping. Researchers and students of species distribution are strongly encouraged to familiarize themselves with all the options of the biomod2 and dismo packages.

Usage

```
ensemble.raster(xn = NULL, ext = NULL,
   models.list = NULL,
   input.weights = models.list$output.weights,
    thresholds = models.list$thresholds,
   RASTER.species.name = "Species001", RASTER.stack.name = xn@title,
   RASTER.format = "raster", RASTER.datatype = "INT2S", RASTER.NAflag = -32767,
   RASTER.models.overwrite = TRUE,
   KML.out = FALSE, KML.maxpixels = 100000, KML.blur = 10,
   evaluate = FALSE, SINK = FALSE,
   p = models.list$p, a = models.list$a,
   pt = models.list$pt, at = models.list$at)
ensemble.habitat.change(base.map=file.choose(),
   other.maps=choose.files(),
   change.folder="ensembles/change",
   RASTER.format = "raster", RASTER.datatype = "INT1U", RASTER.NAflag = 255,
   KML.out = FALSE, KML.folder = "kml/change",
   KML.maxpixels = 100000, KML.blur = 10)
```

Arguments

а

RasterStack object (stack) containing all layers that correspond to explanaхn tory variables of an ensemble calibrated earlier with ensemble.test. See also predict. an Extent object to limit the prediction to a sub-region of xn and the selection of ext background points to a sub-region of x, typically provided as c(lonmin, lonmax, latmin, latmax); see also predict, randomPoints and extent models.list list with 'old' model objects such as MAXENT or RF. input.weights array with numeric values for the different modelling algorithms; if NULL then values provided by parameters such as MAXENT and GBM will be used. As an alternative, the output from ensemble.test.splits can be used. thresholds array with the threshold values separating predicted presence for each of the algorithms. RASTER.species.name First part of the names of the raster files that will be generated, expected to identify the modelled species (or organism). RASTER.stack.name Last part of the names of the raster files that will be generated, expected to identify the predictor stack used. Format of the raster files that will be generated. See writeFormats and writeRaster. RASTER.format RASTER. datatype Format of the raster files that will be generated. See dataType and writeRaster. RASTER.NAflag Value that is used to store missing data. See writeRaster. RASTER.models.overwrite Overwrite the raster files that correspond to each suitability modelling algorithm (if TRUE). (Overwriting actually implies that raster files are created or overwritten that start with "working_"). if FALSE, then no kml layers (layers that can be shown in Google Earth) are KML.out produced. If TRUE, then kml files will be saved in a subfolder 'kml'. KML.maxpixels Maximum number of pixels for the PNG image that will be displayed in Google Earth. See also KML. KML.blur Integer that results in increasing the size of the PNG image by KML.blur^2, which may help avoid blurring of isolated pixels. See also KML. evaluate if TRUE, then evaluate the created raster layers at locations p, a, pt and at (if provided). See also evaluate Append the results to a text file in subfolder 'outputs' (if TRUE). The name of SINK file is based on argument RASTER. species.name. In case the file already exists, then results are appended. See also sink. presence points used for calibrating the suitability models, typically available in р 2-column (x, y) or (lon, lat) dataframe; see also prepareData and extract

background points used for calibrating the suitability models, typically available

in 2-column (x, y) or (lon, lat) dataframe; see also prepareData and extract

presence points used for evaluating the suitability models, typically available in pt 2-column (lon, lat) dataframe; see also prepareData background points used for calibrating the suitability models, typicall available at. in 2-column (lon, lat) dataframe; see also prepareData and extract base.map filename with baseline map used to produce maps that show changes in suitable habitat other.maps files with other maps used to produce maps that show changes in suitable habitat from a defined base.map change.folder folder where new maps documenting changes in suitable habitat will be stored. NOTE: please ensure that the base folder (eg: ../ensembles) exists already. KML.folder folder where new maps (in Google Earth format) documenting changes in suitable habitat will be stored. NOTE: please ensure that the base folder (eg: ../kml) exists already.

Details

The basic function ensemble.raster fits individual suitability models for all models with positive input weights. In subfolder "models" of the working directory, suitability maps for the individual suitability modelling algorithms are stored. In subfolder "ensembles", a consensus suitability map based on a weighted average of individual suitability models is stored. In subfolder "ensembles/presence", a presence-absence (1-0) map will be provided. In subfolder "ensembles/count", a consensus suitability map based on the number of individual suitability models that predict presence of the focal organism is stored.

Several of the features of ensemble.raster are also available from ensemble.test. The main difference between the two functions is that ensemble.raster generates raster layers for individual suitability models, whereas the purpose of ensemble.test is specifically to test different suitability modelling algorithms.

Note that values in suitability maps are integer values that were calculated by multiplying probabilities by 1000 (see also trunc).

As the Mahalanobis function (mahal) does not always provide values within a range of 0 - 1, the output values are rescaled by first subtracting the value of 1 - MAHAL. shape from each prediction, followed by calculating the absolute value, followed by calculating the reciprocal value and finally multiplying this reciprocal value with MAHAL. shape. As this rescaling method does not estimate probabilities, inclusion in the calculation of a (weighted) average of ensemble probabilities may be problematic (the same applies to other distance-based methods).

The ensemble.habitat.change function produces new raster layers that show changes in suitable and not suitable habitat between a base raster and a list of other rasters. The output uses the following coding: 0 = areas that remain unsuitable, 11 = areas that remain suitable, 10 = areas of lost habitat, 1 = areas of new habitat. (Codes are inspired on a binary classification of habitat suitability in base [1- or 0-] and other layer [-1 or -0], eg new habitat is coded 01 = 1).

With KML.out = TRUE, kml files are created in a subfolder named "KML". The colouring of the consensus suitability PNG is based on 20 intervals of size 50 between 0 and 1000. The colouring of the presence-absence PNG uses green for presence and red for absence. The colouring of the count suitability PNG uses black for zero (no models predict presence) and blue for the theoretical maximum number of models to predict presence (i.e. the count of all final weights), whereas intermediate numbers (1 to theoretical maximum - 1) are ranged from red to green. The colouring of the

habitat change maps are: black (cells that are never suitable [value: 0]), green (cells that are always suitable [value: 11]), red (cells that are lost habitat [value: 10] and blue (cells that are new habitat [value: 1]).

Value

The basic function ensemble.raster mainly results in the creation of raster layers that correspond to fitted probabilities of presence of individual suitability models (in folder "models") and consensus models (in folder "ensembles"), and the number of suitability models that predict presence (in folder "ensembles"). Prediction of presence is based on a threshold usually defined by maximizing the sum of the true presence and true absence rates (see threshold.method and also ModelEvaluation).

If desired by the user, the ensemble.raster function also saves details of fitted suitability models or data that can be plotted with the evaluation.strip.plot function.

Arguments

- x RasterStack object (stack) containing all layers that correspond to explanatory variables
- p presence points used for calibrating the suitability models, typically available in 2-column (lon, lat) dataframe; see also prepareData and extract
- a background points used for calibrating the suitability models (except for maxent), typically available in 2-column (lon, lat) dataframe; see also prepareData and extract

an

number of background points for calibration to be selected with randomPoints

in case argument a is missing excludep parameter that indicates (if TRUE) that presence points will be excluded from the background points; see also randomPoints an Extent object to limit the selection of background points to a sub-region of x, ext typically provided as c(lonmin, lonmax, latmin, latmax); see also randomPoints and extent k If larger than 1, the number of groups to split between calibration (k-1) and evaluation (1) data sets (for example, k = 5 results in 4/5 of presence and background points to be used for calibrating the models, and 1/5 of presence and background points to be used for evaluating the models). For ensemble.test.splits, ensemble.test.gbm and ensemble.test.nnet, this procedure is repeated k times (k-fold cross-validation). See also kfold. pt presence points used for evaluating the suitability models, available in 2-column (lon, lat) dataframe; see also prepareData and extract background points used for evaluating the suitability models, available in 2at column (lon, lat) dataframe; see also prepareData and extract TrainData dataframe with first column 'pb' describing presence (1) and absence (0) and other columns containing explanatory variables; see also prepareData. In case that this dataframe is provided, then locations p and a are not used. For the maximum entropy model (maxent), a different dataframe is used for calibration; see parameter MAXENT. TrainData. TestData dataframe with first column 'pb' describing presence (1) and absence (0) and other columns containing explanatory variables; see also prepareData. In case that this dataframe is provided, then locations pt and at are not used. For ensemble.strategy, this dataframe should be a dataframe that contains predictions for various models - such dataframe can be provided by the ensemble. test or ensemble.raster functions. VIF Estimate the variance inflation factors based on a linear model calibrated on the training data (if TRUE). Only background locations will be used and the response variable 'pb' will be replaced by a random variable. See also vif. COR Provide information on the correlation between the numeric explanatory variables (if TRUE). See also cor. SINK Append the results to a text file in subfolder 'outputs' (if TRUE). The name of file is based on argument species. name. In case the file already exists, then results are appended. See also sink. **PLOTS** Plot the results of evaluation for the various suitability models (if TRUE). See also evaluate. threshold.method

Method to calculate the threshold between predicted absence and presence; possibilities include spec_sens (highest sum of the true positive rate and the true negative rate), kappa (highest kappa value), no_omission (highest threshold that corresponds to no omission), prevalence (modeled prevalence is closest to observed prevalence) and equal_sens_spec (equal true positive rate and true negative rate). See threshold. Options specific to the BiodiversityR implementation are: threshold.mean (resulting in calculating the mean value of

spec_sens, equal_sens_spec and prevalence) and threshold.min (resulting in calculating the minimum value of spec_sens, equal_sens_spec and prevalence).

threshold.sensitivity

Sensitivity value for threshold.method = 'sensitivity'. See threshold.

evaluations.keep

Keep the results of evaluations (if TRUE). See also evaluate.

models.list list with 'old' model objects such as MAXENT or RF.

models.keep store the details for each suitability modelling algorithm (if TRUE). (This may be

particularly useful when projecting to different possible future climates.)

models.save Save the list with model details to a file (if TRUE). The filename will be species.name

with extension .models; this file will be saved in subfolder of models. When

loading this file, model results will be available as ensemble.models.

species.name Name by which the model details will be saved to a file; see also argument

models.save

data.keep Keep the data for each k-fold cross-validation run (if TRUE).

AUC. weights If TRUE, then AUC values are used as weights for the ensemble model, scaled to

sum to 1 for the ensemble model through ensemble.weights. If FALSE, then input weights are scaled to sum to 1 for the ensemble model, but AUC values

are not considered.

ENSEMBLE. tune Determine weights for the ensemble model based on AUC values through inter-

nal cross-validation procedures (if TRUE). See details.

ENSEMBLE. best The number of individual suitability models to be used in the consensus suitabil-

ity map (based on a weighted average). In case this parameter is smaller than 1 or larger than the number of positive input weights of individual models, then all individual suitability models with positive input weights are included in the consensus suitability map. In case a vector is provided, ensemble.strategy is

called internally to determine weights for the ensemble model.

ENSEMBLE.min The minimum input weight (assumed to correspond to evaluation indices of

suitability models) for a model to be included in the ensemble. In case a vector is provided, function ensemble.strategy is called internally to determine

weights for the ensemble model.

ENSEMBLE.exponent

Exponent applied to AUC values to convert AUC values into weights (for example, an exponent of 2 converts input weights of 0.7, 0.8 and 0.9 into 0.7^2=0.49,

 $0.8^2=0.64$ and $0.9^2=0.81$). See details.

input.weights array with numeric values for the different modelling algorithms; if NULL then

values provided by parameters such as $\ensuremath{\mathsf{MAXENT}}$ and $\ensuremath{\mathsf{GBM}}$ will be used. As an

alternative, the output from ensemble.test.splits can be used.

MAXENT number: if larger than 0, then a maximum entropy model (maxent) will be fitted

among ensemble

number: if larger than 0, then a boosted regression trees model (gbm) will be

fitted among ensemble

GBMSTEP number: if larger than 0, then a stepwise boosted regression trees model (gbm. step)

will be fitted among ensemble

RF number: if larger than 0, then a random forest model (randomForest) will be fitted among ensemble GLM number: if larger than 0, then a generalized linear model (glm) will be fitted among ensemble **GLMSTEP** number: if larger than 0, then a stepwise generalized linear model (stepAIC) will be fitted among ensemble GAM number: if larger than 0, then a generalized additive model (gam) will be fitted among ensemble **GAMSTEP** number: if larger than 0, then a stepwise generalized additive model (step.gam) will be fitted among ensemble MGCV number: if larger than 0, then a generalized additive model (gam) will be fitted among ensemble MGCVFIX number: if larger than 0, then a generalized additive model with fixed d.f. regression splines (gam) will be fitted among ensemble **EARTH** number: if larger than 0, then a multivariate adaptive regression spline model (earth) will be fitted among ensemble **RPART** number: if larger than 0, then a recursive partioning and regression tree model (rpart) will be fitted among ensemble NNET number: if larger than 0, then an artificial neural network model (nnet) will be fitted among ensemble FDA number: if larger than 0, then a flexible discriminant analysis model (fda) will be fitted among ensemble SVM number: if larger than 0, then a support vector machine model (ksvm) will be fitted among ensemble SVME number: if larger than 0, then a support vector machine model (svm) will be fitted among ensemble BIOCLIM number: if larger than 0, then the BIOCLIM algorithm (bioclim) will be fitted among ensemble DOMAIN number: if larger than 0, then the DOMAIN algorithm (domain) will be fitted among ensemble MAHAL number: if larger than 0, then the Mahalanobis algorithm (mahal) will be fitted among ensemble PROBIT If TRUE, then subsequently to the fitting of the individual algorithm (e.g. maximum entropy or GAM) a generalized linear model (glm) with probit link family=binomial(link="probined probined p will be fitted to transform the predictions, using the previous predictions as explanatory variable. This transformation results in all model predictions to be probability estimates. **GEODIST** number: if larger than 0, then the geoDist algorithm (geoDist) will be fitted among ensemble (note that this algorithm does not use environmental layers, and is based only on the distance from presence points used to calibrate this algorithm) Yweights chooses how cases of presence and background (absence) are weighted; "BIOMOD" results in equal weighting of all presence and all background cases, "equal" results in equal weighting of all cases. The user can supply a vector of weights

similar to the number of cases in the calibration data set.

layer.drops vector that indicates which layers should be removed from RasterStack x. This argument is especially useful for the ensemble. drop1 function. See also addLayer. factors vector that indicates which variables are factors; see also prepareData vector that indicates which variables are dummy variables (influences formulae dummy.vars suggestions) formulae.defaults Suggest formulae for most of the models (if TRUE). See also ensemble. formulae. maxit Maximum number of iterations for some of the models. See also glm.control, gam. control, gam. control and nnet. MAXENT.a background points used for calibrating the maximum entropy model (maxent), typically available in 2-column (lon, lat) dataframe; see also prepareData and extract. Ignored if MAXENT. BackData is provided. MAXENT.an number of background points for calibration to be selected with randomPoints in case argument MAXENT. a is missing MAXENT.BackData dataframe containing explanatory variables for the background locations. This information will be used for calibrating the maximum entropy model (maxent). When used with the ensemble.test.splits function, the same background locations will be used for each of the cross-validation runs; this is based on the assumption that a large number (~10000) of background locations are used. path to the directory where output files of the maximum entropy model are MAXENT.path stored; see also maxent GBM. formula formula for the boosted regression trees algorithm; see also gbm GBM.n.trees total number of trees to fit for the boosted regression trees model; see also gbm GBMSTEP.gbm.x indices of column numbers with explanatory variables for stepwise boosted regression trees; see also gbm. step GBMSTEP.tree.complexity complexity of individual trees for stepwise boosted regression trees; see also gbm.step GBMSTEP.learning.rate weight applied to individual trees for stepwise boosted regression trees; see also gbm.step GBMSTEP.bag.fraction proportion of observations used in selecting variables for stepwise boosted regression trees; see also gbm. step GBMSTEP.step.size number of trees to add at each cycle for stepwise boosted regression trees (should be small enough to result in a smaller holdout deviance than the initial number of trees [50]); see also gbm. step RF.formula formula for random forest algorithm; see also randomForest number of trees to grow for random forest algorithm; see also randomForest RF.ntree RF.mtry number of variables randomly sampled as candidates at each split for random

forest algorithm; see also randomForest

GLM.formula	formula for the generalized linear model; see also glm
GLM.family	description of the error distribution and link function for the generalized linear model; see also ${\tt glm}$
GLMSTEP.steps	maximum number of steps to be considered for stepwise generalized linear model; see also stepAIC
STEP.formula	formula for the "starting model" to be considered for stepwise generalized linear model; see also stepAIC
GLMSTEP.scope	range of models examined in the stepwise search; see also stepAIC
GLMSTEP.k	multiple of the number of degrees of freedom used for the penalty (only $k=2$ gives the genuine AIC); see also stepAIC
GAM.formula	formula for the generalized additive model; see also gam
GAM.family	description of the error distribution and link function for the generalized additive model; see also gam
GAMSTEP.steps	maximum number of steps to be considered in the stepwise generalized additive model; see also step.gam
GAMSTEP.scope	range of models examined in the step-wise search n the stepwise generalized additive model; see also step.gam
GAMSTEP.pos	parameter expected to be set to 1 to allow for fitting of the stepwise generalized additive model
MGCV.formula	formula for the generalized additive model; see also gam
MGCV.select	if TRUE, then the smoothing parameter estimation that is part of fitting can completely remove terms from the model; see also gam
MGCVFIX.formula	
	formula for the generalized additive model with fixed d.f. regression splines; see also gam (the default formulae sets "s(, $fx = TRUE,$)"; see also s)
EARTH.formula	formula for the multivariate adaptive regression spline model; see also earth
EARTH.glm	list of arguments to pass on to glm; see also earth
RPART.formula	formula for the recursive partioning and regression tree model; see also rpart
RPART.xval	number of cross-validations for the recursive partioning and regression tree model; see also rpart.control
NNET.formula	formula for the artificial neural network model; see also nnet
NNET.size	number of units in the hidden layer for the artificial neural network model; see also nnet
NNET.decay	parameter of weight decay for the artificial neural network model; see also nnet
FDA.formula	formula for the flexible discriminant analysis model; see also fda
SVM.formula	formula for the support vector machine model; see also ksvm
SVME.formula	formula for the support vector machine model; see also svm
MAHAL.shape	parameter that influences the transformation of output values of mahal. See details section.
RASTER.format	Format of the raster files that will be generated for the GEODIST model. See writeFormats and writeRaster.

complexity	vector with values of complexity of individual trees (tree.complexity) for boosted regression trees; see also gbm.step
learning	vector with values of weights applied to individual trees (learning.rate) for boosted regression trees; see also ${\sf gbm.step}$
sizes	vector with values of number of units in the hidden layer for the artificial neural network model; see also nnet
decays	vector with values of weight decay for the artificial neural network model; see also nnet
difference	if TRUE, then AUC values of the models with all variables are subtracted from the models where one explanatory variable was excluded. After subtraction, positive values indicate that the model without the explanatory variable has a higher AUC than the model with all variables.
weights	input weights for the ensemble.weights function
best	The number of final weights. In case this parameter is smaller than 1 or larger than the number of positive input weights of individual models, then this parameter is ignored.
min.weight	The minimum input weight to be included in the output.
exponent	Exponent applied to AUC values to convert AUC values into weights (for example, an exponent of 2 converts input weights of 0.7, 0.8 and 0.9 into $0.7^2=0.49$, $0.8^2=0.64$ and $0.9^2=0.81$). See details.
digits	Number of number of decimal places in the output weights; see also round.
verbose	If TRUE, then provide intermediate results for ensemble.strategy)

Details

The basic function ensemble.test first calibrates individual suitability models based on presence locations p and background locations a, then evaluates these suitability models based on presence locations pt and background locations at. While calibrating and testing individual models, results obtained via the evaluate function are shown in the GUI, and possibly plotted (PLOTS) or saved (evaluations.keep).

As an alternative to providing presence locations p, models can be calibrated with data provided in TrainData. In case that both p and TrainData are provided, then models will be calibrated with TrainData.

Calibration of the maximum entropy (MAXENT) algorithm is not based on background locations a, but based on background locations MAXENT.a instead. However, to compare evaluations with evaluations of other algorithms, during evaluations of the MAXENT algorithm, presence locations p and background locations a are used (and not background locations MAXENT.a).

As the Mahalanobis function (mahal) does not always provide values within a range of 0 - 1, the output values are rescaled by first subtracting the value of 1 - MAHAL. shape from each prediction, followed by calculating the absolute value, followed by calculating the reciprocal value and finally multiplying this reciprocal value with MAHAL. shape. As this rescaling method does not estimate probabilities, inclusion in the calculation of a (weighted) average of ensemble probabilities may be problematic (the same applies to other distance-based methods).

With parameter ENSEMBLE.best, the subset of best models (evaluated by the individual AUC values) can be selected and only those models will be used for calculating the ensemble model (in other

words, weights for models not included in the ensemble will be set to zero). It is possible to further increase the contribution to the ensemble model for models with higher AUC values through parameter ENSEMBLE.exponent. With ENSEMBLE.exponent = 2, AUC values of 0.7, 0.8 and 0.9 are converted into weights of $0.7^2=0.49$, $0.8^2=0.64$ and $0.9^2=0.81$). With ENSEMBLE.exponent = 4, AUC values of 0.7, 0.8 and 0.9 are converted into weights of $0.7^4=0.2401$, $0.8^4=0.4096$ and $0.9^2=0.6561$).

ENSEMBLE. tune will result in an internal procedure whereby the best selection of parameter values for ENSEMBLE.min, ENSEMBLE.best or ENSEMBLE.exponent can be identified. Through a factorial procedure, the ensemble model with best AUC for a specific combination of parameter values is identified. The procedure also provides the weights that correspond to the best ensemble.

Function ensemble.test.splits splits the presence and background locations in a user-defined (k) number of subsets (i.e. k-fold cross-validation), then sequentially calibrates individual suitability models with (k-1) combined subsets and evaluates those with the remaining one subset, whereby each subset is used once for evaluation in the user-defined number (k) of runs. For example, k = 5 results in splitting the locations in 5 subsets, then using one of these subsets in turn for evaluations (see also kfold). Note that for the maximum entropy (MAXENT) algorithm, the same background data will be used in each cross-validation run (this is based on the assumption that a large number (~10000) of background locations are used).

Among the output from function ensemble.test.splits are suggested weights for an ensemble model (output.weights and output.weights.AUC), and information on the respective AUC values of the ensemble model with the suggested weights for each of the (k) subsets. Suggested weights output.weights are calculated as the average of the weights of the different algorithms (submodels) of the k ensembles. Suggested weights output.weights.AUC are calculated as the average of the AUC of the different algorithms of the for the k runs.

Function ensemble.test.gbm allows to test various combinations of parameters tree.complexity and learning.rate for the gbm.step model.

Function ensemble.test.nnet allows to test various combinations of parameters size and decay for the nnet model.

Function ensemble.drop1 allows to test the effects of leaving out each of the explanatory variables, and comparing these results with the "full" model. Note that option of difference = TRUE may result in positive values, indicating that the model without the explanatory variable having larger AUC than the "full" model. A procedure is included to estimate the deviance of a model based on the fitted values, using -2 * (sum(x*log(x)) + sum((1-x)*log(1-x))) where x is a vector of the fitted values for a respective model. (It was checked that this procedure results in similar deviance estimates for the null and 'full' models for glm, but note that it is not certain whether deviance can be calculated in a similar way for other submodels.)

Function ensemble. formulae provides suggestions for formulae that can be used for ensemble. test and ensemble.raster. This function is always used internally by the ensemble.drop1 function.

The ensemble.weights function is used internally by the ensemble.test and ensemble.raster functions, using the input weights for the different suitability modelling algorithms. Ties between input weights result in the same output weights.

The ensemble.strategy function is used internally by the ensemble.test and ensemble.raster functions, using the train and test data sets with predictions of the different suitability modelling algorithms and different combinations of parameters ENSEMBLE.best, ENSEMBLE.min and ENSEMBLE.exponent. The final ensemble model is based on the parameters that generate the best AUC.

Value

Function ensemble.test (potentially) returns a list with results from evaluations (via evaluate) of calibration and test runs of individual suitability models.

Function ensemble.test.splits returns a matrix with, for each individual suitability model, the AUC of each run and the average AUC over the runs. Models are sorted by the average AUC. The average AUC for each model can be used as input weights for the ensemble.raster function.

Functions ensemble.test.gbm and ensemble.test.nnet return a matrix with, for each combination of model parameters, the AUC of each run and the average AUC. Models are sorted by the average AUC.

Description

These functions provide a dataframe which can subsequently be used to evaluate the relationship between environmental variables and the fitted probability of occurrence of individual or ensemble suitability modelling algorithms. The biomod2 package provides an alternative implementation of this approach (response.plot2).

Usage

```
evaluation.strip.data(xn = NULL, ext = NULL,
    models.list = NULL,
    input.weights = models.list$output.weights,
    vars = models.list$vars, factors = models.list$factors,
    dummy.vars = models.list$dummy.vars,
    steps=50
)
```

evaluation.strip.data 79

```
evaluation.strip.plot(data,
    modelnames = c("MAXENT", "GBM", "GBMSTEP", "RF", "GLM", "GLMSTEP", "GAM",
        "GAMSTEP", "MGCV", "MGCVFIX", "EARTH", "RPART", "NNET", "FDA",
        "SVM", "SVME", "BIOCLIM", "DOMAIN", "MAHAL"),
    variable = NULL, model = NULL, ...
)
```

Arguments

xn	RasterStack object (stack) containing all layers that correspond to explanatory variables of an ensemble calibrated earlier with ensemble.test. See also predict.
ext	an Extent object to limit the prediction to a sub-region of xn and the selection of background points to a sub-region of x, typically provided as c(lonmin, lonmax, latmin, latmax); see also predict, randomPoints and extent
models.list	list with 'old' model objects such as MAXENT or RF.
input.weights	array with numeric values for the different modelling algorithms; if NULL then values provided by parameters such as MAXENT and GBM will be used. As an alternative, the output from ensemble.test.splits can be used.
vars	Vector that indicates which variables should be included as columns in the data frame. Only variables that correspond to layers of the rasterStack will be included.
factors	vector that indicates which variables are factors; see also prepareData and ensemble.formulae
dummy.vars	vector that indicates which variables are dummy variables (coded 0 or 1 to indicate presence of specific level of a categorical variable; see also ensemble.formulae
steps	number of steps within the range of a continuous explanatory variable
data	data set with ranges of environmental variables and fitted suitability models, typically returned by evaluation.strip.data
modelnames	abbreviated names of the individual suitability models that are fitted. Should correspond to the names used in ensemble.grd.
variable	focal explanatory variable for plots with evaluation strips
model	focal model for plots with evaluation strips
	Other arguments passed to plot

Details

These functions are mainly intended to be used internally by the ensemble raster function.

evaluation.strip.data creates a data frame with variables (columns) corresponding to the environmental variables encountered in the RasterStack object (x) and the suitability modelling approaches that were defined. The variable of focal.var is an index of the variable for which values are ranged. The variable of categorical is an index for categorical (factor) variables.

80 evaluation.strip.data

A continuous (numeric) variable is ranged between its minimum and maximum values in the number of steps defined by argument steps. When a continuous variable is not the focal variable, then the average (mean) is used.

A categorical (factor) variable is ranged for all the encountered levels (levels) for this variable. When a categorical variable is not the focal variable, then the most frequent level is used.

Value

function evaluation.strip.data creates a data frame, function codeevaluation.strip.data allows for plotting.

faramea

Faramea occidentalis abundance in Panama

Description

This dataset describes the abundance (number of trees with diameter at breast height equal or larger than 10 cm) of the tree species Faramea occidentalis as observed in a 1-ha quadrat survey from the Barro Colorada Island of Panama. For each quadrat, some environmental characteristics are also provided.

Usage

```
data(faramea)
```

Format

A data frame with 45 observations on the following 8 variables.

```
UTM.EW a numeric vector UTM.NS a numeric vector
```

82 ifri

```
Precipitation a numeric vector

Elevation a numeric vector

Age a numeric vector

Age.cat a factor with levels c1 c2 c3

Geology a factor with levels pT Tb Tbo Tc Tcm Tgo Tl
```

Faramea.occidentalis a numeric vector

Details

Although the original survey documented tree species composition of all 1-ha subplots of larger (over 1 ha) sample plot, only the first (and sometimes the last) quadrats of the larger plots were included. This selection was made to avoid that larger sample plots dominated the analysis. This selection of sites is therefore different from the selection of the 50 1-ha quadrats of the largest sample plot of the same survey (BCI and BCI.env)

This dataset is the main dataset used for the examples provided in chapters 6 and 7 of the Tree Diversity Analysis manual (Kindt & Coe, 2005).

Examples

data(faramea)

ifri

Example data from the International Forestry Resources and Institutions (IFRI) research network importancevalue 83

Description

This data set contains information on the number of stems (individuals) and basal areas for 34 vegetation plots inventoried in February 1997 in Lothlorien forest, 37 vegetation plots inventoried in February 1996 in May Creek Forest and 36 vegetation plots inventoried in May 1995 in Yellowwood State Forest. All three sites are in Indiana, USA. Data were gathered through IFRI inventory protocols to record any tree, palm and woody climber with diameter at breast height greater than or equal to 10 cm in 10-m radius circular plots; only tree species data were kept in the example data sets (IFRI research instruments and IFRI manual section P: Forest Plot Form, section D1: Tree, Palm and Woody Climber Information).

Usage

data(ifri)

Format

A data frame with 486 observations on the following 5 variables.

forest a factor with 3 levels: "LOT" (Lothlorien forest), "MCF" (May Creek Forest) and "YSF" (Yellowwood State Forest)

plotID a factor with 107 levels providing an identification code for a 314.16 square metres (10 m radius) vegetation plot

species a factor with 50 levels providing an 8 character code for a tree species

count a numeric vector providing the number of stems (individuals) for each species in each vegetation plot

basal a numeric vector providing the basal area (calculated from the diameter at breast height) in square cm for each species in each vegetation plot

importancevalue

Importance Value

Description

Calculates the importance values of tree species based on frequency (calculated from number of plots), density (calculated from number of individuals) and dominance (calculated from basal area). See details.

84 importancevalue

Usage

Arguments

X	data frame with information on plot identities, species identities, number of individuals and basal areas
site	factor variable providing the identities of survey plots
species	factor variable providing the identities of tree species
count	number of individuals for each tree species in each survey plot
basal	basal area for each tree species in each survey plot
factor	factor variable used to define subsets (typically different forest reserves)
level	level of the factor variable used to create a subset from the original data

Details

The importance value is calculated as the sum from (i) the relative frequency; (ii) the relative density; and (iii) the relative dominance. The importance value ranges between 0 and 300.

Frequency is calculated as the number of plots where a species is observed divided by the total number of survey plots. Relative frequency is calculated by dividing the frequency by the sum of the frequencies of all species, multiplied by 100 (to obtain a percentage).

Density is calculated as the total number of individuals of a species. Relative density is calculated by dividing the density by the sum of the densities of all species, multiplied by 100 (to obtain a percentage).

Dominance is calculated as the total basal area of a species. Relative dominance is calculated by dividing the dominance by the sum of the dominance of all species, multiplied by 100 (to obtain a percentage).

Functions importancevalue.comp applies function importancevalue to all available levels of a factor variable.

Value

Provides information on the importance value for all tree species

loaded.citations

Give Citation Information for all Loaded Packages

Description

This function provides citation information for all loaded packages.

Usage

```
loaded.citations()
```

Details

The function checks for the loaded packages via .packages. Citation information is provided for the base package and for all the non-standard packages via citation.

Value

The function provides a list of all loaded packages and the relevant citation information.

Author(s)

Roeland Kindt (World Agroforestry Centre)

Description

Makes a community data set from a stacked dataset (with separate variables for the site identities, the species identities and the abundance).

Usage

makecommunitydataset(x,row,column,value,factor="",level="",drop=F)

Arguments

X	Data frame.
row	Name of the categorical variable for the rows of the crosstabulation (typically indicating sites)
column	Name of the categorical variable for the columns of the crosstabulation (typically indicating species)
value	Name of numerical variable for the cells of the crosstabulation (typically indicating abundance). The cells provide the sum of all values in the data frame.
factor	Name of the variable to calculate a subset of the data frame.
level	Value of the subset of the factor variable to calculate a subset of the data frame.
drop	Drop rows without species (species with total abundance of zero are always dropped)

Details

This function calculates a cross-tabulation from a data frame, summing up all the values of the numerical variable identified as variable for the cell values. If factor="", then no subset is calculated from the data frame in the first step.

Value

The function provides a community dataset from another data frame.

http://www.worldagroforestry.org/resources/databases/tree-diversity-analysis

Examples

multiconstrained

Pairwise Comparisons for All Levels of a Categorical Variable by RDA, CCA or Capscale

Description

This function implements pairwise comparisons for categorical variable through capscale, cca or rda followed by anova.cca. The function simply repeats constrained ordination analysis by selecting subsets of data that correspond to two factor levels.

Usage

```
multiconstrained(method="capscale", formula, data, distance = "bray"
, comm = NULL, add = FALSE, multicomp="", contrast=0, ...)
```

Arguments

method	Method for constrained ordination analysis; one of "rda", "cca"or "capscale".
formula	Model formula as in capscale, cca or rda. The LHS can be a community data matrix or a distance matrix for capscale.
data	Data frame containing the variables on the right hand side of the model formula as in capscale, cca or rda.
distance	Dissimilarity (or distance) index in vegdist used if the LHS of the formula is a data frame instead of dissimilarity matrix; used only with function vegdist and partial match to "manhattan", "euclidean", "canberra", "bray", "kulczynski", "jaccard", "gower", "morisita", "horn" or "mountford". This argument is only used for capscale in case that the LHS of the formula is a community matrix.
comm	Community data frame which will be used for finding species scores when the LHS of the formula was a dissimilarity matrix as only allowed for capscale. This is not used if the LHS is a data frame.
add	Logical indicating if an additive constant should be computed, and added to the non-diagonal dissimilarities such that all eigenvalues are non-negative in underlying Principal Co-ordinates Analysis; only applicable in capscale.

88 multiconstrained

multicomp	Categorical variable used to construct the contrasts from. In case that this variable is missing, then the first explanatory variable of the formula will be used.
contrast	Return the ordination results for the particular contrast indicated by this number (e.g. with 5 levels, one can choose in between contrast 1-10). In case=0, then the first row of the anova.cca results for all contrasts is provided.
	Other parameters passed to anova, cca.

Details

This function provides a simple expansion of capscale, cca and rda by conducting the analysis for subsets of the community and environmental datasets that only contain two levels of a categoricl variable.

When the choice is made to return results from all contrasts (contrast=0), then the first row of the anova.cca tables for each contrast are provided. It is therefore possible to compare differences in results by modifying the "by" argument of this function (i.e. obtain the total of explained variance, the variance explained on the first axis or the variance explained by the variable alone).

When the choice is made to return results from a particular contrast (contrast>0), then the ordination result is returned and two new datasets ("newcommunity" and "newenvdata") are created that only contain data for the two selected contrasts.

Value

The function returns an ANOVA table that contains the first rows of the ANOVA tables obtained for all possible combinations of levels of the first variable. Alternatively, it returns an ordination result for the selected contrast and creates two new datasets ("newcommunity" and "newenvdata")

Examples

nested.anova.dbrda 89

##	End	Not	run)

nested.anova.dbrda Nested Analysis of Variance via Distance-based Redundancy Analysis or Non-parametric Multivariate Analysis of Variance

Description

The functions provide nested analysis of variance for a two-level hierarchical model. The functions are implemented by estimating the correct F-ratio for the main and nested factors (assuming the nested factor is random) and using the recommended permutation procedures to test the significance of these F-ratios. F-ratios are estimated from variance estimates that are provided by distance-based redundancy analysis (capscale) or non-parametric multivariate analysis of variance (adonis).

Usage

```
nested.anova.dbrda(formula, data, method="euc", add=FALSE,
    permutations=100, warnings=FALSE)
nested.npmanova(formula, data, method="euc", permutations=100, warnings=FALSE)
```

Arguments

formula	Formula with a community data frame (with sites as rows, species as columns and species abundance as cell values) or (for nested.anova.dbrda only) distance matrix on the left-hand side and two categorical variables on the right-hand side (with the second variable assumed to be nested within the first).
data	Environmental data set.
method	Method for calculating ecological distance with function <code>vegdist</code> : partial match to "manhattan", "euclidean", "canberra", "bray", "kulczynski", "jaccard", "gower", "morisita", "horn" or "mountford". This argument is ignored in case that the left-hand side of the formula already is a distance matrix.
add	Should a constant be added to the off-diagonal elements of the distance-matrix (TRUE) or not.
permutations	The number of permutations for significance testing.
warnings	Should warnings be suppressed (TRUE) or not.

Details

The functions provide two alternative procedures for multivariate analysis of variance on the basis of any distance measure. Function nested.anova.dbrda proceeds via capscale, whereas nested.npmanova proceeds via adonis. Both methods are complementary to each other as nested.npmanova always provides correct F-ratios and estimations of significance, whereas nested.anova.dbrda does not provide correct F-ratios and estimations of significance when negative eigenvalues are encountered or constants are added to the distance matrix, but always provides an ordination diagram.

The F-ratio for the main factor is estimated as the mean square of the main factor divided by the mean square of the nested factor. The significance of the F-ratio of the main factor is tested by

90 NMSrandom

permuting entire blocks belonging to levels of the nested factor. The significance of the F-ratio of the nested factor is tested by permuting sample units within strata defined by levels of the main factor.

Value

The functions provide an ANOVA table.

Examples

NMSrandom

Calculate the NMS Result with the Smallest Stress from Various Random Starts

Description

This function provides a simplified version of the method of calculating NMS results implemented by the function metaMDS (vegan).

Usage

```
NMSrandom(x,perm=100,k=2,stressresult=F,method="isoMDS")
```

NMSrandom 91

Arguments

x	Distance matrix.
perm	Number of permutations to select the configuration with the lowest stress.
k	Number of dimensions for the non metric scaling result; passed to isoMDS or sammon.
stressresult	Provide the calculated stress for each permutation.
method	Method for calculating the NMS: isoMDS or sammon.

Details

This function is an easier method of calculating the best NMS configuration after various random starts than implemented in the metaMDS function (vegan). The function uses a distance matrix (as calculated for example by function vegdist from a community data set) and calculates random starting positions by function initMDS (vegan) analogous to metaMDS.

Value

The function returns the NMS ordination result with the lowest stress (calculated by isoMDS or sammon.), or the stress of each NMS ordination.

Examples

92 nnetrandom

nnetrandom	Calculate the NNET Result with the Smallest Value from Various Random Starts

Description

This function provides the best solution from various calls to the nnet feed-forward artificial neural networks function (nnet).

Usage

```
nnetrandom(formula,data,tries=10,leave.one.out=F,...)
```

Arguments

formula Formula as passed to nnet.

data Data as passed to nnet.

tries Number of calls to nnet to obtain the best solution.

leave.one.out Calculate leave-one-out predictions.

Other arguments passed to nnet.

Details

This function makes various calls to nnet. If desired by the user, leave-one-out statistics are provided that report the prediction if one particular sample unit was not used for iterating the networks.

Value

The function returns the same components as nnet, but adds the following components:

range Summary of the observed "values".

tries Number of different attempts to iterate an ANN.

CV Predicted class when not using the respective sample unit for iterating ANN.

succesful Test whether leave-one-out statistics provided the same class as the original class.

ordicoeno

Coenoclines for an Ordination Axis

Description

A graph is produced that summarizes (through GAM as implemented by gam) how the abundance of all species of the community data set change along an ordination axis (based on the position of sites along the axis and the information from the community data set).

Usage

```
ordicoeno(x, ordiplot, axis = 1, legend = FALSE, cex = 0.8, ncol = 4, ...)
```

Arguments

X	Community data frame with sites as rows, species as columns and species abundance as cell values.
ordiplot	Ordination plot created by ordiplot.
axis	Axis of the ordination graph (1: horizontal, 2: vertical).
legend	if TRUE, then add a legend to the plot.
cex	the amount by which plotting text and symbols should be magnified relative to the default; see also par
ncol	the number of columns in which to set the legend items; see also legend
	Other arguments passed to functions plot and points.

94 ordisymbol

Details

This functions investigates the relationship between the species vectors and the position of sites on an ordination axis. A GAM (gam) investigates the relationship by using the species abundances of each species as response variable, and the site position as the explanatory variable. The graph shows how the abundance of each species changes over the gradient of the ordination axis.

Value

The function plots coenoclines and provides the expected degrees of freedom (complexity of the relationship) estimated for each species by GAM.

```

ordisymbol

Add Other Graphical Items to Ordination Diagrams

Description

Functions to add some other graphical itmes to ordination diagrams than provided within **vegan** by ordihull, ordispider, ordiarrows, ordisegments, ordigrid, ordiellipse, ordicluster and lines.spantree.

Usage

```
ordisymbol(ordiplot, y, factor, col = 1, rainbow = TRUE,
    legend = TRUE, legend.x = "topleft", legend.ncol = 1, ...)
ordibubble(ordiplot,var,...)
ordicluster2(ordiplot, cluster, mingroups = 1, maxgroups = nrow(ordiplot$sites), ...)
ordinearest(ordiplot, dist,...)
ordivector(ordiplot, spec, lty=2,...)
```

ordisymbol 95

Arguments

ordiplot An ordination graph created by ordiplot (vegan).

y Environmental data frame.

factor Variable of the environmental data frame that defines subsets to be given differ-

ent symbols.

var Continuous variable of the environmental dataset or species from the community

dataset.

col Colour (as points).
rainbow Use rainbow colours.
legend Add the legend.

legend.x Location of the legend; see also legend.

legend.ncol the number of columns in which to set the legend items; see also legend

cluster Cluster object.

mingroups Minimum of clusters to be plotted.

maxgroups Maximum of clusters to be plotted...

dist Distance matrix.

spec Species name from the community dataset.

1ty Line type as specified for par.

... Other arguments passed to functions points, symbols, ordihull or arrows.

Details

Function ordisymbol plots different levels of the specified variable in different symbols and different colours (if rainbow option was selected).

Function ordibubble draws bubble diagrams indicating the value of the specified continuous variable. Circles indicate positive values, squares indicate negative values.

Function ordicluster2 provides an alternative method of overlaying information from hierarchical clustering on an ordination diagram than provided by function ordicluster. The method draws convex hulls around sites that are grouped into the same cluster. You can select the minimum and maximum number of clusters that are plotted (i.e. the range of clustering steps to be shown).

Function ordinearest draws a vector from each site to the site that is nearest to it as determined from a distance matrix. When you combine the method with lines.spantree using the same distance measure, then you can evaluate in part how the minimum spanning tree was constructed.

Function ordivector draws a vector for the specified species on the ordination diagramme and draws perpendicular lines from each site to a line that connects the origin and the head of species vector. This method helps in the biplot interpretation of a species vector as described by Jongman, ter Braak and van Tongeren (1995).

Value

These functions add graphical items to an existing ordination diagram.

96 PCA significance

```

PCAsignificance

PCA Significance

Description

Calculates the number of significant axes from a Principal Components Analysis based on the broken-stick criterion, or adds an equilibrium circle to an ordination diagram.

Usage

```
PCAsignificance(pca,axes=8) ordiequilibriumcircle(pca,ordiplot,...)
```

Arguments

рса	Principal Components Analysis result as calculated by rda (vegan).
axes	Number of axes to calculate results for.
ordiplot	Ordination plot created by ordiplot (vegan)
	Other arguments passed to function arrows.

PCAsignificance 97

Details

These functions provide two methods of providing some information on significance for a Principal Components Analysis (PCA).

Function PCAsignificance uses the broken-stick distribution to evaluate how many PCA axes are significant. This criterion is one of the most reliable to check how many axes are significant. PCA axes with larger percentages of (accumulated) variance than the broken-stick variances are significant (Legendre and Legendre, 1998).

Function ordiequilibriumcircle draws an equilibrium circle to a PCA ordination diagram. Only species vectors with heads outside of the equilibrium circle significantly contribute to the ordination diagram (Legendre and Legendre, 1998). Vectors are drawn for these species. The function considers the scaling methods used by rda for scaling=1. The method should only be used for scaling=1 and PCA calculated by function rda.

Value

Function PCAsignificance returns a matrix with the variances that are explained by the PCA axes and by the broken-stick criterion.

Function ordiequilibriumcircle plots an equilibrium circle and returns a list with the radius and the scaling constant used by rda.

98 radfitresult

radfitresult	Alternative Rank Abundance Fitting Results
I ddi I ti touI t	Thiermanive Rank Houndance I tilling Results

Description

Provides alternative methods of obtaining rank abundance curves than provided by functions radfit, fisherfit and prestonfit (**vegan**), although these same functions are called.

Usage

```
radfitresult(x,y="",factor="",level,plotit=T)
```

Arguments

X	Community data frame with sites as rows, species as columns and species abundance as cell values.
У	Environmental data frame.
factor	Variable of the environmental data frame that defines subsets to calculate fitted rank-abundance curves for.
level	Level of the variable to create the subset to calculate fitted rank-abundance curves.
plotit	Plot the results obtained by plot.radfit.

Details

These functions provide some alternative methods of obtaining fitted rank-abundance curves, although functions radfit, fisherfit and prestonfit (vegan) are called to calculate the actual results.

Value

The function returns the results from three methods of fitting rank-abundance curves:

```
radfit results of radfit.
fisherfit results of fisherfit.
prestonfit results of prestonfit.
```

Optionally, a plot is provided of the radfit results by plot.radfit.

rankabundance

Rank Abundance Curves

Description

Provides methods of calculating rank-abundance curves.

Usage

```
\label{eq:continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous
```

Arguments

X	Community data frame with sites as rows, species as columns and species abundance as cell values.
У	Environmental data frame.
factor	Variable of the environmental data frame that defines subsets to calculate rank abundance curves for.
level	Level of the variable to create the subset to calculate rank abundance curves.
digits	Number of digits in the results.
t	t-value to calculate confidence interval limits for the species proportion for cluster sampling (following Hayek and Buzas 1997).
xr	Result from rankabundance.
addit	Add rank abundance curve to an existing graph.
labels	Labels to plot at left of the rank abundance curves.
scale	Method of scaling the vertical axis. Method "abundance" uses abundance, "proportion" uses proportional abundance (species abundance / total abundance), "logabun" calculates the logarithm of abundance using base 10 and "accumfreq" accumulates the proportional abundance.
scaledx	Scale the horizontal axis to 100 percent of total number of species.
type	Type of plot (as in function plot)
xlim	Limits for the horizontal axis.
ylim	Limits for the vertical axis.

100 rankabundance

specnames Vector positions of species names to add to the rank-abundance curve.

rainbow Use rainbow colouring for the different curves.

legend Add the legend (you need to click in the graph where the legend needs to be

plotted).

. . . Other arguments to be passed to functions plot or points.

Details

These functions provide methods of calculating and plotting rank-abundance curves.

The vertical axis can be scaled by various methods. Method "abundance" uses abundance, "proportion" uses proportional abundance (species abundance / total abundance), "logabun" calculates the logarithm of abundance using base 10 and "accumfreq" accumulates the proportional abundance.

The horizontal axis can be scaled by the total number of species, or by 100 percent of all species by option "scaledx".

The method of calculating the confidence interval for species proportion is described in Hayek and Buzas (1997).

Functions rankabundance and rankabuncomp allow to calculate rank abundance curves for subsets of the community and environmental data sets. Function rankabundance calculates the rank abundance curve for the specified level of a selected environmental variable. Method rankabuncomp calculates the rank abundance curve for all levels of a selected environmental variable separatedly.

Value

The functions provide information on rankabundance curves. Function rankabundance provides information on abundance, proportional abundance, logarithmic abundance and accumulated proportional abundance. The function also provides confidence interval limits for the proportion of each species (plower, pupper) and the proportion of species ranks (in percentage).

removeNAcomm 101

removeNAcomm

Synchronize Community and Environmental Datasets

Description

These functions may assist to ensure that the sites of the community dataset are the same sites as those from the environmental dataset, something that is assumed to be the case for the **BiodiversityR** and **vegan** packages.

Usage

```
same.sites(x, y)
check.datasets(x, y)
check.ordiscores(x, ord, check.species = TRUE)
removeNAcomm(x, y, variable)
removeNAenv(x, variable)
removezerospecies(x)
subsetcomm(x, y, factor, level, returncomm = TRUE)
```

Arguments

Х	Data frame assumed to be the community dataset with variables corresponding to species.
у	Data frame assumed to be the environmental dataset with variables corresponding to descriptors of sites.
ord	Ordination result.
check.species	Should the species scores be checked (TRUE) or not.
variable	Name of the variable from the environmental dataset with NA values that indicate those sites that should be removed.
factor	Variable of the environmental data frame that defines subsets for the data frame.
level	Level of the variable to create the subsets for the data frame.
returncomm	For the selected sites, return the community dataset (TRUE) or the environmental dataset.

102 removeNAcomm

Details

Function same.sites provides a new data frame that has the same row names as the row names of the environmental data set and the same (species) variables as the original community data set. Sites from the original community data set that have no corresponding sites in the environmental data set are not included in the new community data set. (Hint: this function can be especially useful when some sites do not contain any species and where a community dataset was generated by the makecommunitydataset function.)

Function check.datasets checks whether the community and environmental data sets have the same number of rows, and (if this was the case) whether the rownames of both data sets are the same. The function also returns the dimensions of both data sets.

Function check.ordiscores checks whether the community data set and the ordination result have the same number of rows (sites) and columns (species, optional for check.species==TRUE), and (if this was the case) whether the row and column names of both data sets are the same. Site and species scores for the ordination result are obtained via function scores (vegan).

Functions removeNAcomm and removeNAenv provide a new data frame that does not contain NA for the specified variable. The specified variable is part of the environmental data set. These functions are particularly useful when using community and environmental datasets, as new community and environmental datasets can be calculated that contain information from the same sample plots (sites). An additional result of removeNAenv is that factor levels of any categorical variable that do not occur any longer in the new data set are removed from the levels of the categorical variable.

Function removezerospecies removes species from a community dataset that have total abundance that is smaller or equal to zero.

Function subsetcomm makes a subset of sites that contain a specified level of a categorical variable from the environmental data set. The same functionality of selecting subsets of the community or environmental data sets are implemented in various functions of **BiodiversityR** (for example diversityresult, renyiresult and accumresult) and have the advantage that it is not necessary to create a new data set. If a community dataset is returned, species that did not contain any individuals were removed from the data set. If an environmental dataset is returned, factor levels that did not occur were removed from the data set.

Value

The functions return a data frame or results of tests on the correspondence between community and environmental data sets.

check.datasets(dune4,dune5)</pre>
```

renyiresult

Alternative Renyi Diversity Results

Description

Provides some alternative methods of obtaining results on Renyi diversity profile values than provided by renyi (**vegan**).

Usage

Arguments

x Community data frame with sites as rows, species as columns and species abundance as cell values.

y Environmental data frame.

factor Variable of the environmental data frame that defines subsets to calculate diversity profiles for.

104 renyiresult

level Level of the variable to create the subset to calculate diversity profiles.

method Method of calculating the diversity profiles: "all" calculates the diversity of the

entire community (all sites pooled together), "s" calculates the diversity of each

site separatedly.

scales Scale parameter values as in function renyi (vegan).

evenness Calculate or plot the evenness profile.

xr Result from renyi or renyiresult.

addit Add diversity profile to an existing graph.

pch Symbol used for drawing the diversity profiles (as in function points).

xlab Label for the horizontal axis.
ylab Label for the vertical axis.
ylim Limits of the vertical axis.

labelit Provide site labels (site names) at beginning and end of the diversity profiles.

legend Add the legend (you need to click in the graph where the legend needs to be

plotted).

col Colour for the diversity profile (as in function points).

cex Character expansion factor (as in function points).

rainbow Use rainbow colours for the diversity profiles.

sites Maximum number of sites to provide profile values.

permutations Number of permutations for the Monte-Carlo simulations for accumulated renyi

diversity profiles (estimated by renyiaccum).

plotit Plot the results (you need to click in the graph where the legend should be plot-

ted).

... Other arguments to be passed to functions renyi or plot.

Details

These functions provide some alternative methods of obtaining results with diversity profiles, although function renyi is always used to calculate the diversity profiles.

The method of calculating the diversity profiles: "all" calculates the diversity profile of the entire community (all sites pooled together), whereas "s" calculates the diversity profile of each site separatedly. The evenness profile is calculated by subtracting the profile value at scale 0 from all the profile values.

Functions renyiresult, renyiaccumresult and renyicomp allow to calculate diversity profiles for subsets of the community and environmental data sets. functions renyiresult and renyiaccumresult calculate the diversity profiles for the specified level of a selected environmental variable. Method renyicomp calculates the diversity profile for all levels of a selected environmental variable separatedly.

Functions renyicomp and renyiaccumresult calculate accumulation curves for the Renyi diversity profile by randomised pooling of sites and calculating diversity profiles for the pooled sites as implemented in renyiaccum. The method is similar to the random method of species accumulation (specaccum). If the number of "sites" is not changed from the default, it is replaced by the sample size of the level with the fewest number of sites.

residualssurface 105

Value

The functions provide alternative methods of obtaining Renyi diversity profiles.

residualssurface

Show and Interpolate Two Dimensional Distribution of Residuals

Description

This function interpolates the spatial structure of residuals of a GLM through gam or surf.ls and optionally provides a graph.

106 residualssurface

Usage

```
residualssurface(model, data, x, y, gam = F, npol = 2, plotit = T, filled = F, bubble = F)
```

Arguments

model	Result of GLM as calculated by glm or glm.nb.
data	Data set that contains the spatial coordinates of the sample units used for the original model (specified as "x" and "y").
x	Horizontal position of the sample units.
У	Vertical position of the sample units.
gam	Interpolate the spatial structure by gam (if "TRUE") or by surf.ls (if "FALSE").
npol	Degree of polynomial surface as passed to surf.ls.
plotit	Plot the interpolated surface (through interp and the residuals).
filled	Fill the contours by filled.contour.
bubble	Provide a bubble graph of the residuals: circles indicate positive residuals, whereas squares indicate negative residuals.

Details

The function reports the results of a GAM or least-squares trend surface analysis of the spatial distribution of residuals of a model (through residuals).

Optionally, a graph is produced that can contain the trend surface, filled contours and bubble graphs in addition to the spatial location of the sample units.

Value

The function reports the results of a GAM or least-squares trend surface analysis of the spatial distribution of residuals. Optionally, a graph is provided.

Examples

spatialsample 107

spatialsample

Spatial Sampling within a Polygon

Description

Spatial sampling within a polygon provides several methods of selecting rectangular sample plots within a polygon. Using a GIS package may be preferred for actual survey design.

Usage

```
spatialsample(x,method="random",n=5,xwidth=0.5,ywidth=0.5,xleft=0,
    ylower=0,xdist=0,ydist=0,plotit=T,plothull=F)
```

Arguments

Х	2-column matrix with the coordinates of the vertices of the polygon. The first column contains the horizontal (x) position, the second column contains the vertical (y) position.
method	Method of sampling, any of "random", "grid" or "random grid".
n	Number of sample plots to be selected, or number of horizontal and vertical grid positions.
xwidth	Horizontal width of the sample plots.
ywidth	Vertical width of the sample plots.
xleft	Horizontal starting position of the grid.
ylower	Vertical starting position of the grid.
xdist	Horizontal distance between grid locations.
ydist	Vertical distance between grid locations.
plotit	Plot the sample plots on the current graph.
plothull	Plot a convex hull around the sample plots.

Details

Spatial sampling within a polygon provides several methods of selecting the position of sample plots.

Method "random" selects random positions of the sample plots using simple random sampling.

Method "grid" selects sample plots from a grid defined by "xleft", "ylower", "xdist" and "ydist". In case xdist=0 or ydist=0, then the number of grid positions are defined by "n". In case "xleft" or "ylower" are below the minimum position of any vertix of the polygon, then a random starting position is selected for the grid.

Method "random grid" selects sample plots at random from the sampling grid using the same methods of defining the grid as for method "grid".

108 transfgradient

Value

The function returns a list of centres of rectangular sample plots.

```

transfgradient

Gradient for Hypothetical Example of Turover of Species Composition

Description

This dataset documents the site sequence of 19 sites on a gradient determined from unimodal species distributions. The dataset is accompanied by transfspecies that documents the species composition of the sites. This is a hypothetical example that allows to investigate how well ecological distance measures or ordination methods recover the expected best sequence of sites.

Usage

```
data(transfgradient)
```

transfspecies 109

Format

A data frame with 19 observations on the following variable.

```
gradient a numeric vector
```

Source

Legendre, P. & Gallagher, E.D. (2001) Ecologically meaningful transformations for ordination of species data. Oecologia 129: 271-280.

References

Figure 3a.

Examples

transfspecies

Hypothetical Example of Turover of Species Composition

Description

This dataset documents the species composition of 19 sites that follow a specific sequence of sites as determined from unimodal species distributions. The dataset is accompanied by transfgradient that documents the gradient in species turnover. This is a hypothetical example that allows to investigate how well ecological distance measures or ordination methods recover the expected best sequence of sites.

Usage

```
data(transfspecies)
```

Format

A data frame with 19 observations on the following 9 variables.

```
species1 a numeric vector
species2 a numeric vector
species3 a numeric vector
species4 a numeric vector
species5 a numeric vector
species6 a numeric vector
```

```
species7 a numeric vector
species8 a numeric vector
species9 a numeric vector
```

Details

The example in the Tree Diversity Analysis manual only looks at the ecological distance from the first site. Hence, only the first 10 sites that share some species with this site should be selected.

This dataset enables investigations of how well ecological distance measures and ordination diagrams reconstruct the gradient (sequence of sites). The gradient expresses how the sites would be arranged based on their species composition.

Examples

warcom

Warburgia ugandensis AFLP Scores

Description

This data set contains scores for 185 loci for 100 individuals of the Warburgia ugandensis tree species (a medicinal tree species native to Eastern Africa). Since the data set is a subset of a larger data set that originated from a study of several Warburgia species, some of the loci did not produce bands for W. ugandensis (i.e. some loci only contain zeroes). This data set is accompanied by warenv that describes population and regional structure of the 100 individuals.

Usage

```
data(warcom)
```

Warburgia ugandensis Population Structure

Description

This data set contains population and regional locations for 100 individuals of the Warburgia ugandensis tree species (a medicinal tree species native to Eastern Africa). This data set is associated with warcom that contains scores for 185 AFLP loci.

Usage

```
data(warenv)
```

Format

A data frame with 100 observations on the following 4 variables.

population a factor with levels Kibale Kitale Laikipia Lushoto Mara popshort a factor with levels KKIT KLAI KMAR TLUS UKIB country a factor with levels Kenya Tanzania Uganda rift.valley a factor with levels east west
